## **Solution Small Angle X-ray Scattering: Basic Principles and Experimental Aspects**

**Xiaobing Zuo (NCI-Frederick)**

**Alex Grishaev (NIDDK)**

# 1. General Aspects

- History
- Study scope
- X-ray scattering vs neutron and light scattering

# History of X-ray and scattering

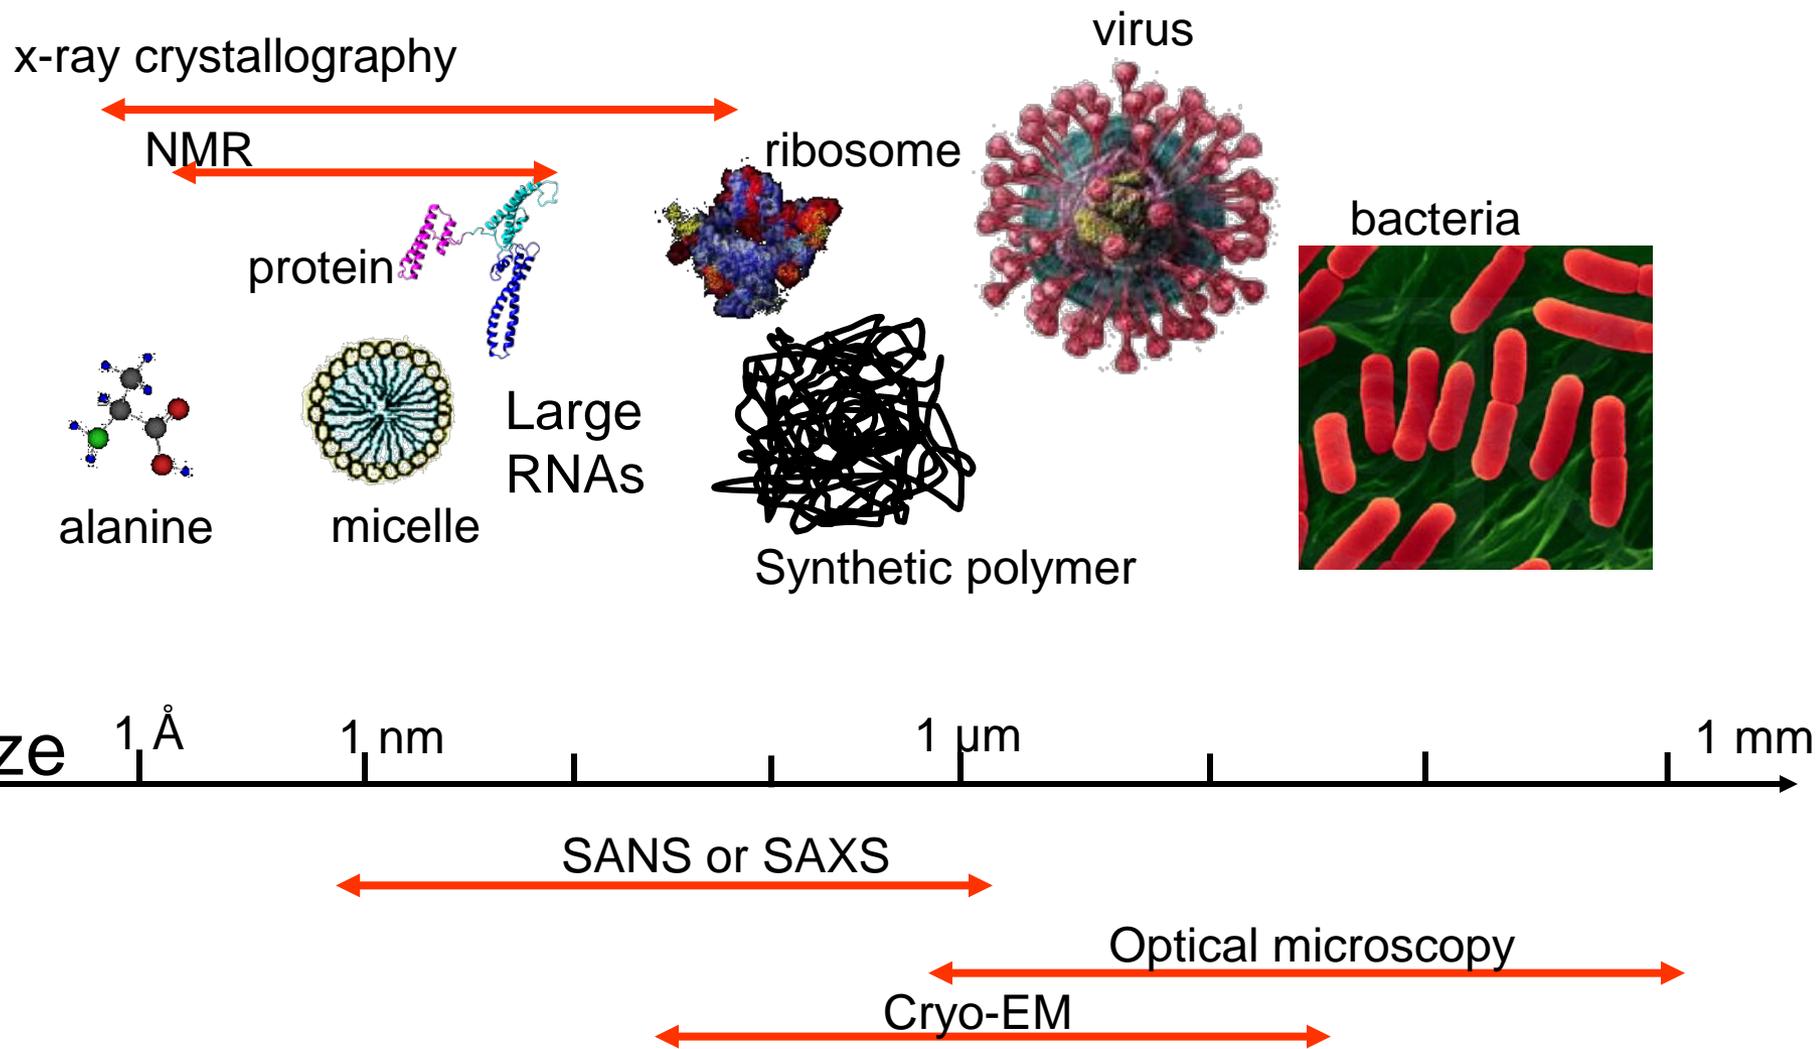

- ▶ X-ray discovered in 1895

Wilhelm Conrad Röntgen 1845-1923

- ▶ First solution X-ray scattering performed in late 1930s
  - ▶ Measure molecular weight, size
- ▶ For a long time, applications had been limited by available X-ray source, detector and data analysis methods

# Scales of various methods

The scope of small angle X-ray scattering in terms of spatial dimension covers ~1nm to ~1μm ranges, perfectly suitable for biomolecular structural study.

# X-ray scattering vs. neutron, light scattering

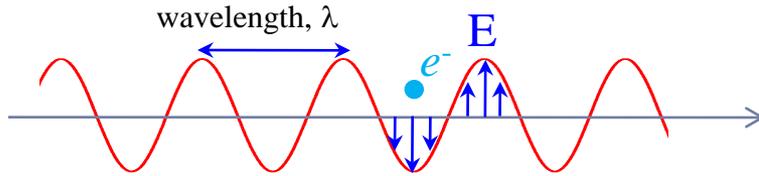

- ▶ **Solution scattering techniques**
  - ▶ Small-angle X-ray scattering (SAXS)
  - ▶ Small-angle neutron scattering (SANS)
  - ▶ Small-angle light scattering (LS)
- ▶ **Interaction with objects**
  - ▶ X-ray and light interact with electrons
  - ▶ Neutron scattering: nuclear spins
- ▶ **Wavelength / probe scale**
  - ▶ Light scattering:  $\lambda$ : 2000 – 8000 Å
  - ▶ Neutron scattering: 5 – 20 Å
  - ▶ X-ray scattering:  $\lambda$ : 0.5 – 2.0 Å
- ▶ **Provided information**
  - ▶ Sizes,
  - ▶ Shapes
  - ▶ Low resolution structure
  - ▶ higher resolution for shorter wavelength

## **2. Physics of X-ray scattering**

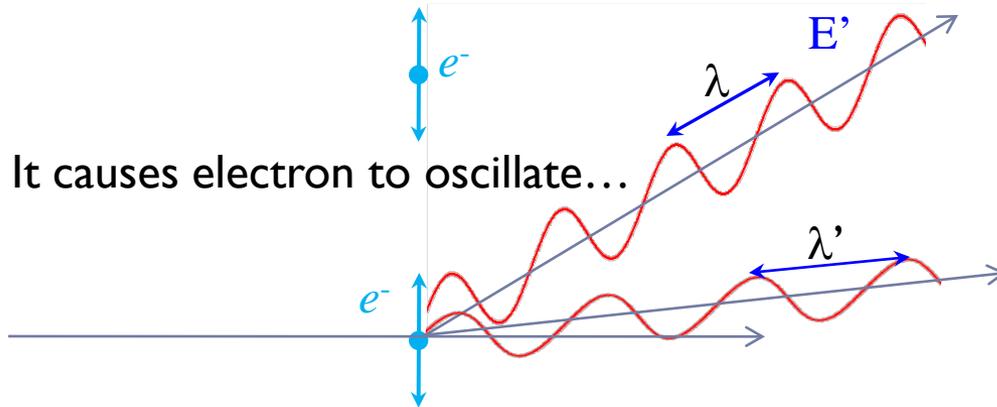

- Scattering phenomenon and interference
- From crystal and fiber diffraction to solution scattering
- X-ray contrasting
- Form factor and object shapes
- Theory on solution scattering calculations

# Scattering phenomenon and interference

X-ray is traveling wave...

X-ray electric field hits electron...

It causes electron to oscillate...

And make it radiate secondary X-ray!  
This is scattering!

X-ray Wave function:

$$E(t) = E_0 e^{i(2\pi\nu t + \phi_0)}$$

frequency:  $\nu = c/\lambda$

Initial phase:  $\phi_0$

Phase change:  $\Delta\phi = 2\pi d/\lambda$  (radian)  
after travelling distance  $d$ .

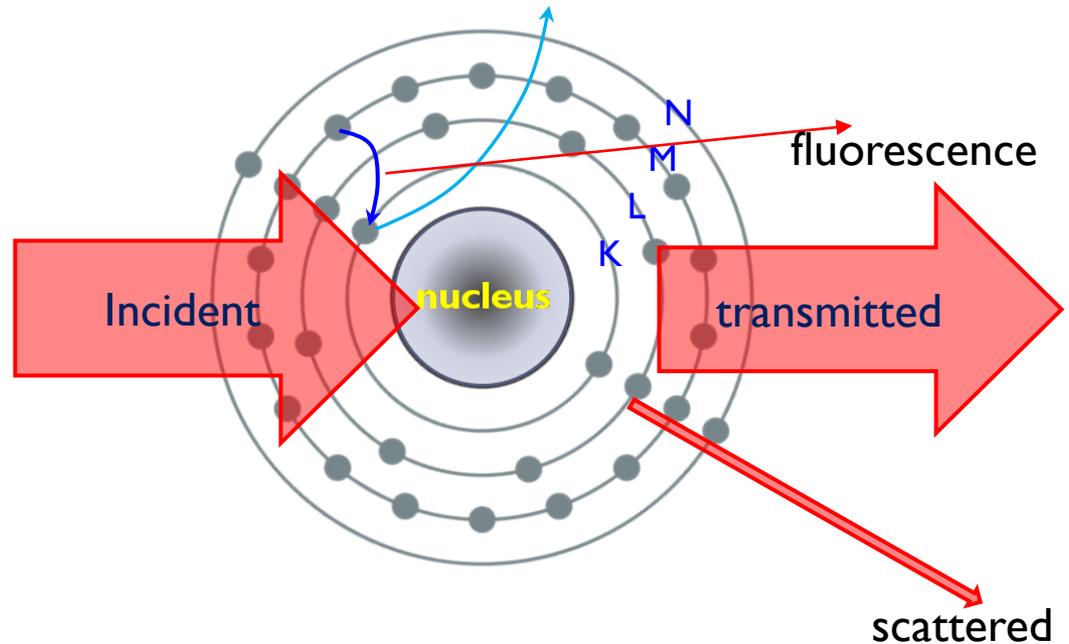

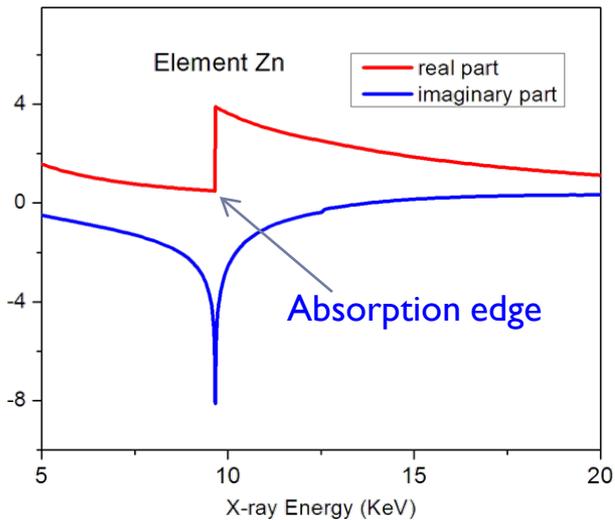

Elastic scattering:  $\lambda \rightarrow \lambda$  not change

Inelastic (Compton) scattering:  $\lambda \rightarrow \lambda'$  changed

If the scattered X-ray has the same wavelength of the original X-ray, it is called elastic/coherent scattering (no energy loss). If the wavelength of the scattering is changed (longer), it is inelastic/incoherent/Compton scattering (there is an energy loss)

# X-ray interacts with atoms

Inelastic scattering is very weak and often ignorable for bound electrons, for example electron in atoms. Besides elastic and inelastic scattering, atoms absorb X-ray and emit fluorescence X-ray, especially at the absorption edges.

- Fluorescence X-ray has lower energy or longer wavelength due to energy loss.
- Both Inelastic scattering and fluorescence X-ray only add background to scattering data because they don't interfere with elastically scattering x-ray due to different wavelength!
- However, stay away the absorption edges when choose X-ray radiation energy for scattering to avoid problematic fluorescence X-ray background.

# X-ray measures distance/structure by interference

## ➤ Interference in pond:

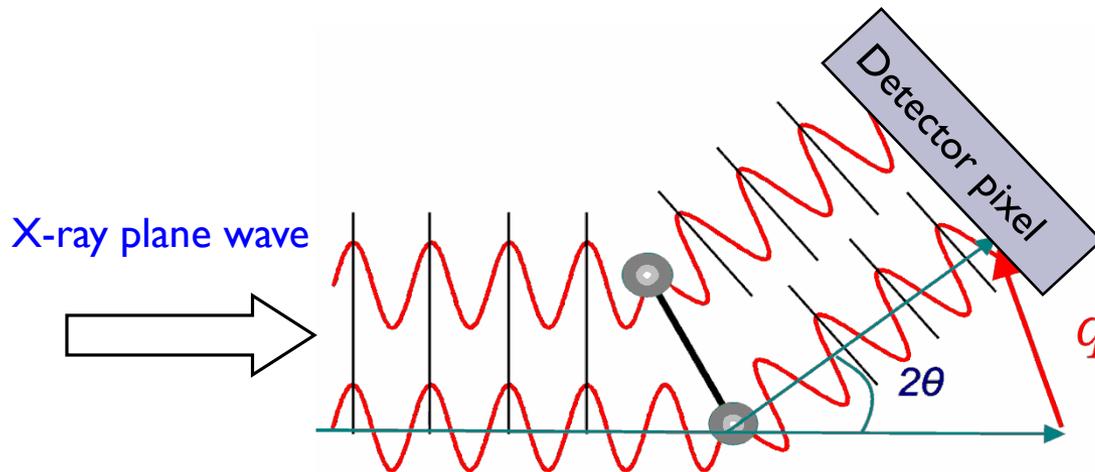

Interference pattern of water waves codes distance between sources

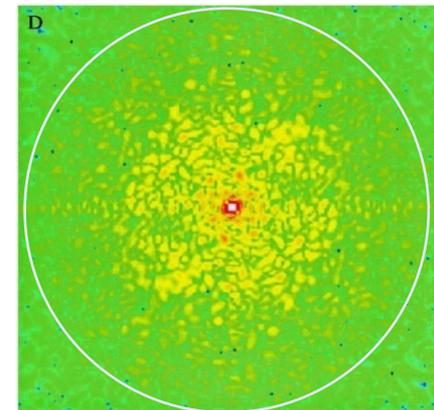

## ➤ Elastic scattering Interference:

Elastic X-ray scattering interferes.

Before hit the scatterers, the X-ray plane waves travel with same phase (in phase). When hit the scatterers, X-ray waves are scattered. When two scattered X-ray waves arrive at a detector pixel with same phase (they are in phase), they enhance each other (constructive interference). If they arrive a pixel with opposite phases (out of phase), they cancel each other (deconstructive interference). The interference pattern on detector encodes the distances among scatterers.

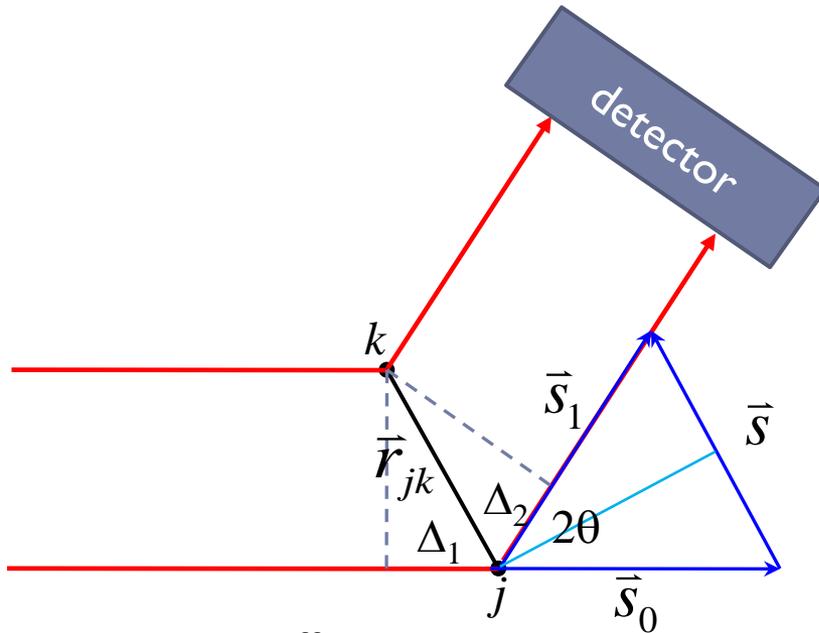

X-ray wave Interference pattern

# Phase change and Momentum transfer

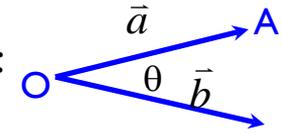

The phase difference between two scattered X-ray beams is determined by the difference of distance they traveled before arrive the detector pixel.

A vector  $\vec{a}$  has its length  $a = |\vec{a}|$  and direction (O→A).

Vector dot product:

$$\vec{a} \cdot \vec{b} = a * b \cos(\theta)$$

unit incident wavevector  $\vec{s}_0$   
 unit scattering wavevector  $\vec{s}_1$   
 wave vector change:  $\vec{s}$

$$\vec{s} = \vec{s}_1 - \vec{s}_0$$

$$|\vec{s}| = 2 \sin \theta$$

Total distance difference:

$$\begin{aligned} \Delta &= \Delta_1 + \Delta_2 = -\vec{s}_0 \cdot \vec{r}_{jk} + \boxed{\vec{s}_1 \cdot \vec{r}_{jk}} \quad \text{Projection of } \vec{r}_{jk} \text{ on } \vec{s}_1 \\ &= (\vec{s}_1 - \vec{s}_0) \cdot \vec{r}_{jk} = \vec{s} \cdot \vec{r}_{jk} \end{aligned}$$

Definition: momentum transfer

$$\vec{q} = (2\pi / \lambda) \vec{s}$$

$$q = |\vec{q}| = (4\pi / \lambda) \sin \theta$$

Phase change:  
(radian)

$$\Delta\phi = 2\pi * \frac{\Delta}{\lambda} = \vec{q} \cdot \vec{r}_{jk}$$

# Scattering by an electron pair

**Amplitude** at  $q$  of scattered X-ray by electron  $j$  at position  $\vec{r}_j$ :

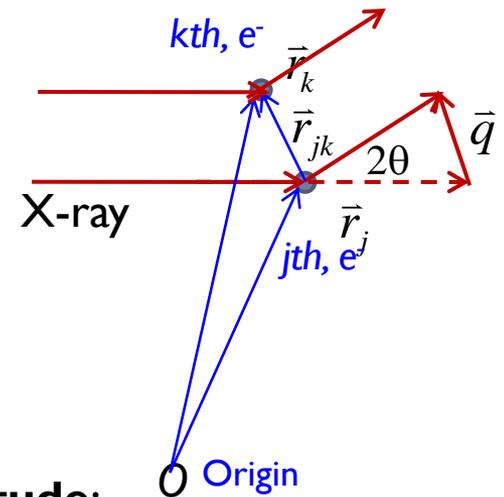

Wave function  $E'(t) = E_0' e^{i(2\pi\nu t + \phi_0)} \boxed{e^{i\vec{q} \cdot \vec{r}_j}} \iff A_j(\vec{q}) = f_e \exp(i\vec{q} \cdot \vec{r}_j)$   
additional phase change

Total amplitude at  $q$  of scattered X-ray by electrons  $j$  &  $k$ :

$$\begin{aligned} A_{tot}(\vec{q}) &= A_j(\vec{q}) + A_k(\vec{q}) = f_e \exp(i\vec{q} \cdot \vec{r}_j) + f_e \exp(i\vec{q} \cdot \vec{r}_k) \\ &= f_e \exp(i\vec{q} \cdot \vec{r}_j) \{1 + \exp[i\vec{q} \cdot (\vec{r}_k - \vec{r}_j)]\} \\ &= f_e \exp(i\vec{q} \cdot \vec{r}_j) \left\{ \underbrace{1 + \cos(\vec{q} \cdot \vec{r}_{jk})}_{\text{real}} + \underbrace{i \sin(\vec{q} \cdot \vec{r}_{jk})}_{\text{imaginary}} \right\} \end{aligned}$$

**Intensity** registered on detector is the **square of the amplitude**:

$$\begin{aligned} I(\vec{q}) &= |A_{tot}(\vec{q})|^2 = A_{tot}(\vec{q}) A_{tot}^*(\vec{q}) \\ &= f_e^2 \left| \exp(i\vec{q} \cdot \vec{r}_j) \right|^2 \times \left| 1 + \cos(\vec{q} \cdot \vec{r}_{jk}) + i \sin(\vec{q} \cdot \vec{r}_{jk}) \right|^2 \\ &= f_e^2 \times 1 \times \left[ \underbrace{1+1}_{\text{from individuals}} + \underbrace{2 \cos(\vec{q} \cdot \vec{r}_{jk})}_{\text{cross/ interference term}} \right] \end{aligned}$$

- Scattering intensity does not remember/care where the Origin we choose, but is a function of scatterer pair distance(s), which is the structural information.
- Loss of phase information during measuring
- The interference pattern comprises the contribution from individual electrons (scatterers), and more importantly the cross term from each and every scatterer pair

In principle, interference pattern of an object with  $N$   $e^-$ :

$$I(\vec{q}) = \left| \sum_{j=1}^N A_j(\vec{q}) \right|^2 = \left| \sum_{j=1}^N f_e \exp(i\vec{q} \cdot \vec{r}_j) \right|^2$$

# From crystal and fiber diffraction to solution scattering

Interference patterns of objects vary along with the samples' nature, including the symmetry of matrix of molecules embedded and the freedom of molecules in the matrix.

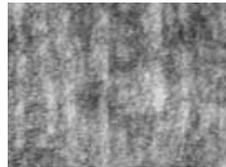

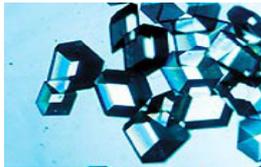

**Single Crystal**

**Fiber/  
Membrane**

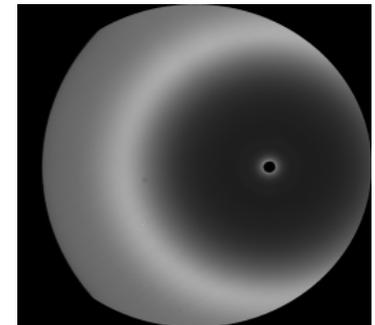

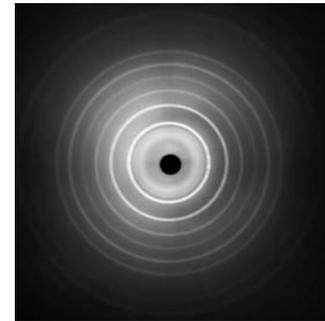

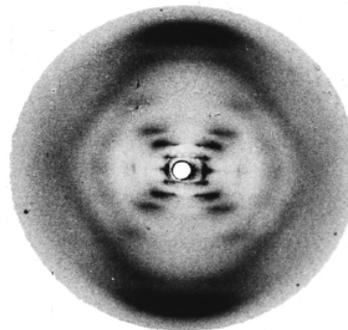

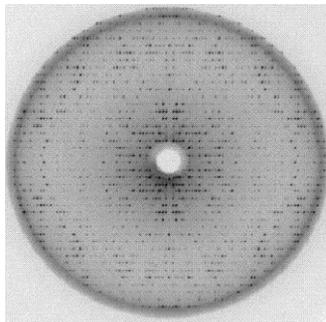

**Powder/  
Micro-crystals**

**Solution**

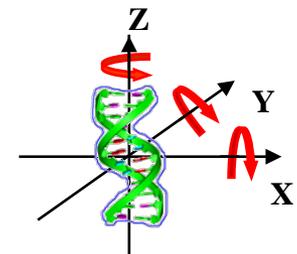

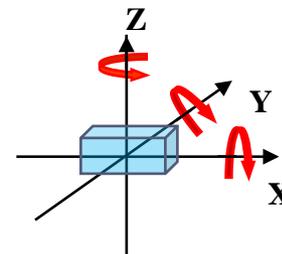

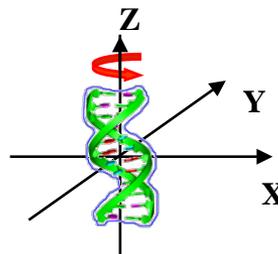

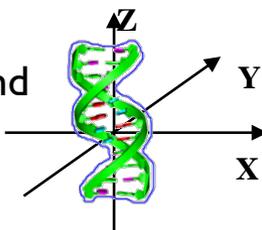

Sample states

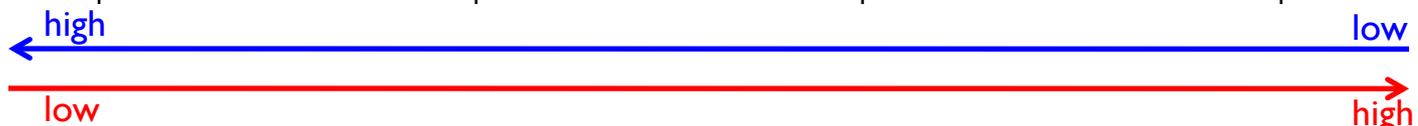

Interference pattern

matrix symmetry and molecular freedom

Matrix symmetry  
Molecular freedom

# X-ray scattering form factor/scattering length

$$I(\vec{q}) = \left| \sum_{j=1}^N A_j(\vec{q}) \right|^2 = \left| \sum_{j=1}^N f_e \exp(i\vec{q} \cdot \vec{r}_j) \right|^2$$

- In reality, it is impossible to find the positions of each electrons in an object, then calculate the scattering / interference pattern. We can divide the object into small relative independent units (e.g atoms) and calculate the pattern from those small units.
- X-ray scattering length/form factor represent the capability of an object scatters X-ray. The scattering length of an electron is  $f_e = 2.8179 \times 10^{-13} \text{cm}^{-1}$ . For the sake of simplicity,  $f_e$  set as a unit:  $f_e \equiv 1$ .

For an object with an ensemble of N electrons:

Define:  $F(\vec{q}) = \sum_{j=1}^N f_e \exp(i\vec{q} \cdot \vec{r}_j)$

$$I(\vec{q}) = \left| \sum_j A_j(\vec{q}) \right|^2 = \left| \sum_j f_e \exp(i\vec{q} \cdot \vec{r}_j) \right|^2 \equiv F^2(\vec{q})$$

Scattering form factor/length

$$\left| \frac{F(\vec{q})}{f_e} \right|^2 = \left| \frac{I(\vec{q})}{I_e} \right|$$

If a scatterer can take all the orientation:

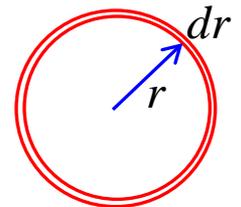

$$I(q) = \langle I(\vec{q}) \rangle_{\Omega} \quad \langle \exp(i\vec{q} \cdot \vec{r}_j) \rangle_{\Omega} = \frac{\sin(qr)}{qr}$$

average over  
all orientation

Loss of the direction the momentum  
transfer/ angular term

For an object with radially uniform electron density  $\rho(r)$ :

$$F(q) = \sum_j \underbrace{(4\pi r^2 dr)}_{\text{Total electrons between two spherical surfaces}} \rho(r) \langle \exp(i\vec{q} \cdot \vec{r}_j) \rangle_{\Omega} = 4\pi \int \rho(r) r^2 \frac{\sin(qr)}{qr} dr$$

# form factor for sphere

The form factors of some objects with simple shapes have analytical formula expression, for example, sphere. Sphere is a widely used model in characterizing the size or size distribution of globular particles in structural biology and nanoscale material science.

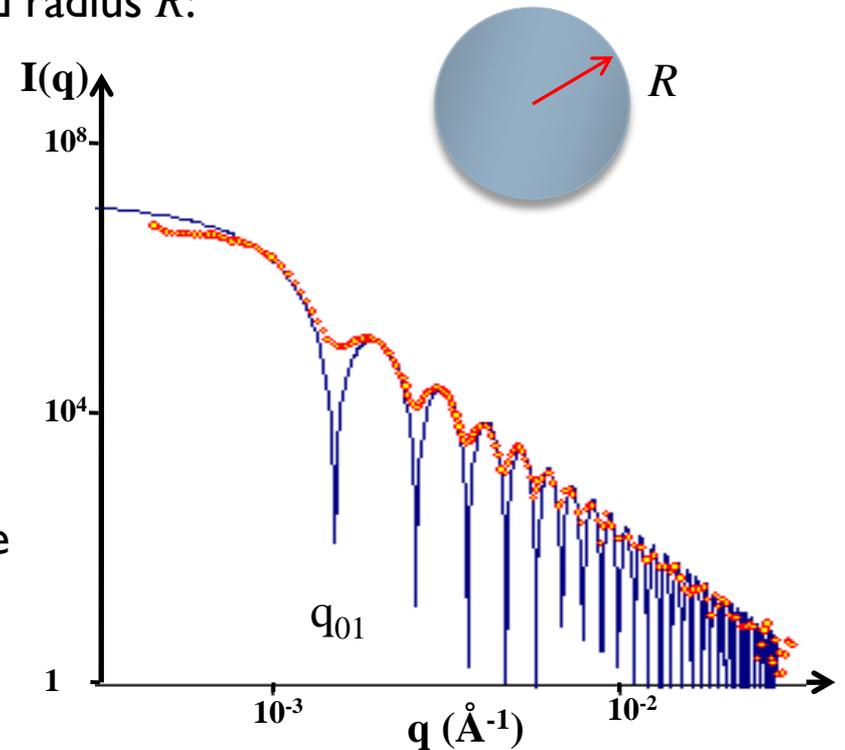

Sphere with homogenous electron density and radius  $R$ :

$$F(q) = \frac{3(\sin(qR) - qR \cos(qR))}{(qR)^3}$$

$$I(q) = F^2(q) = \left( \frac{3(\sin(qR) - qR \cos(qR))}{(qR)^3} \right)^2$$

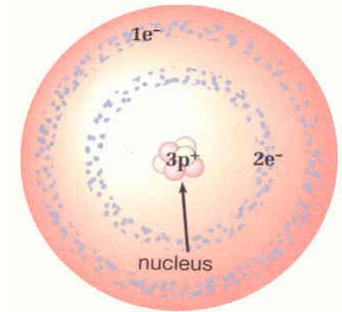

From the scattering curve, we can estimate the radius of the sphere:

$$R \approx \frac{4.493}{q_{01}}$$

- Scattering profile of silica spheres (red) and simulation based on perfect sphere (blue)
- Discrepancy of silica scattering from sphere model due to size polydispersity, imperfect spherical shape, etc.

# Atomic form factor

Atomic electron cloud

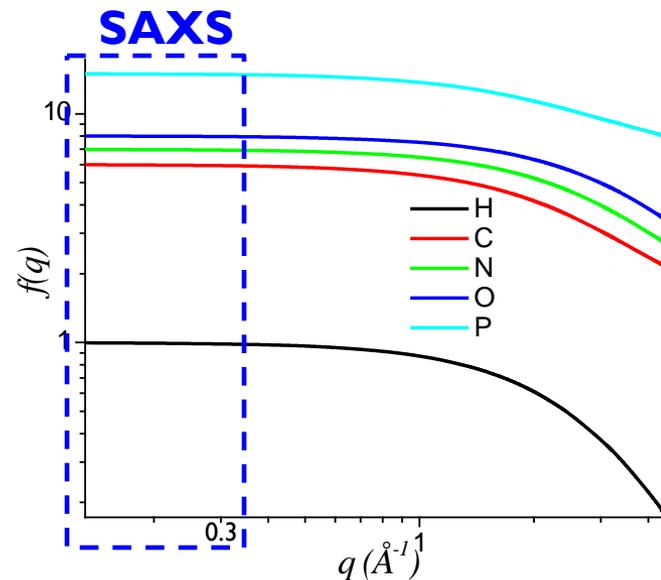

Atomic form factors are fundamental parameters in X-ray techniques.

Electron cloud in atoms has radial density distribution  $\rho(r)$

$$f(q) = 4\pi \int \rho(r) r^2 \frac{\sin(qr)}{qr} dr$$

$\rho(r)$  were obtained from quantum chemical calculations. Atomic form factors for all elements and important ions were tabulated in International Tables for Crystallography and other handbooks.

- $f(0)=Z$  : the total electron of the atom.
- Atoms with higher  $Z$  will scatter stronger.
- $f(q)$  decreases slowly along  $q$  in region (SAXS) of  $q$  close to 0
- In low-resolution model reconstruction from SAXS data using  $f(q)=\text{const}$

Data taken from International Tables for Crystallography, Vol. C, Table 6.1.1.1

# Solution X-ray scattering measures the contrast / electron density difference

In vacuum, x-ray scattering directly measures Z number.

Solution sample scattering:

$$I_{molecule} = I_{solution} - I_{solvent}$$

What X-ray scattering measures:

$$\Delta\rho(\vec{r}) = \rho_m(\vec{r}) - \rho_s(\vec{r})$$

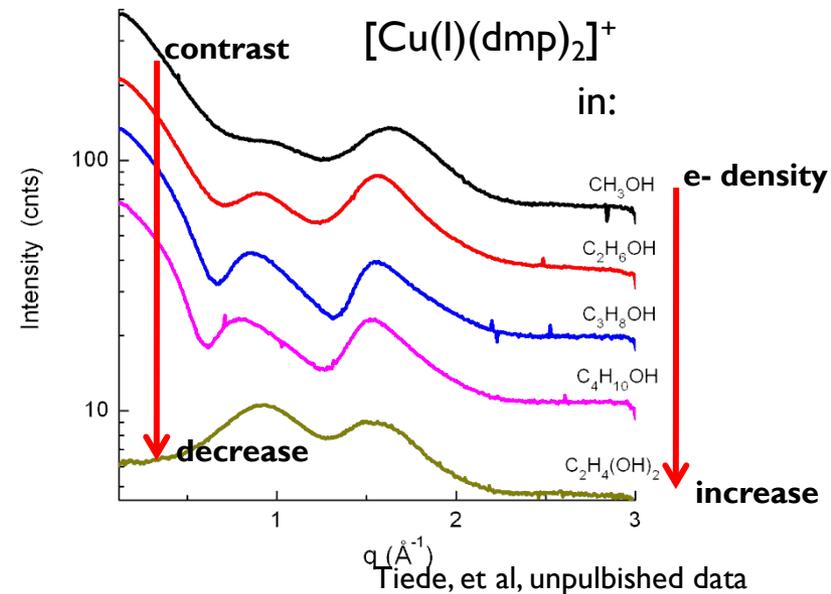

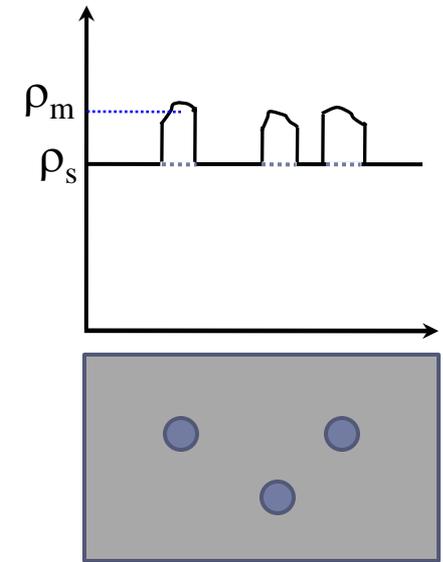

excess electron density/scattering length against solvent/buffer

In vacuum:  $A(\vec{r}) = \rho_m(\vec{r})e^{i\vec{q}\cdot\vec{r}}$

In solution:  $A(\vec{r}) = \Delta\rho(\vec{r})e^{i\vec{q}\cdot\vec{r}}$

Solution X-ray scattering contrast matching:

Increasing solvent electron density, X-ray scattering contrast match occurs at average spatial scale  $[l(q \sim 0) \rightarrow 0]$ , but electron density difference still exist locally / at high spatial resolution scale.

# Theory on molecular solution X-ray scattering calculations

Atomic apparent form factor / contrast :

$$A_j(q) = f_j(q) - g_j(q)$$

↑ atomic form factor in vacuum
← form factor of excluded solvent

X-ray scattering total amplitude:

$$\sum_j A_j \exp(i\vec{q} \cdot \vec{r}_j)$$

In solution, X-ray beam sees all orientations of molecules :

$$I(q) = \langle I(\vec{q}) \rangle_{\Omega} = \left\langle \left\langle \sum_j A_j \exp(i\vec{q} \cdot \vec{r}_j) \right\rangle \right\rangle_{\Omega}^2$$

← loss of phase information
← loss of angular direction

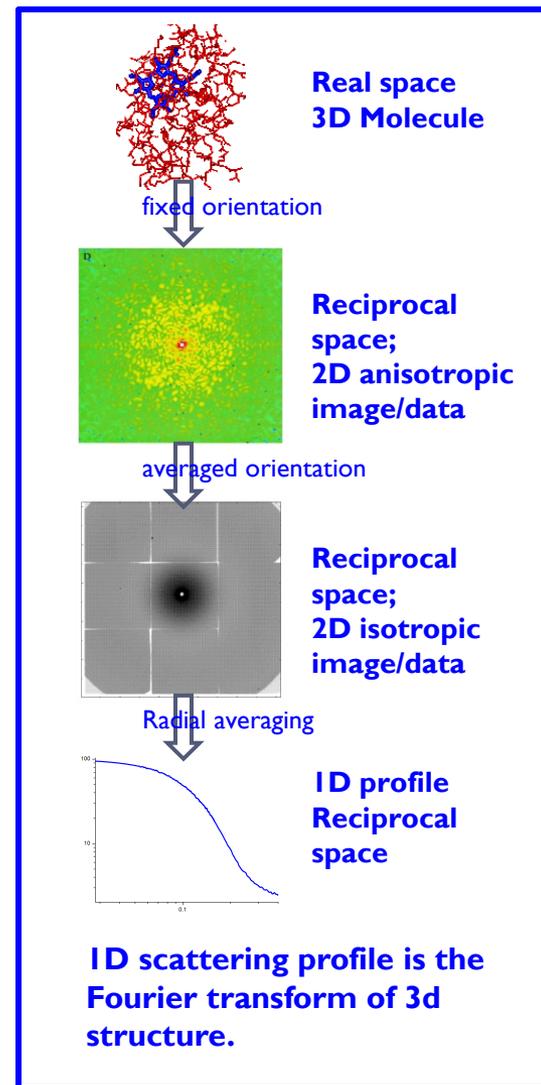

$$= \sum_j \sum_k A_j A_k \frac{\sin(qr_{jk})}{qr_{jk}} = \boxed{\sum_j A_j^2} + \boxed{2 \sum_j \sum_{k>j} A_j A_k \frac{\sin(qr_{jk})}{qr_{jk}}}$$

Atom pair distance / Structural information

Individual contribution

interference

Solution x-ray scattering is a 1D profile which encodes molecular structural information.

# 3. Experimental Aspects of Scattering

# Where do the lab X-rays come from?

Rotating anode source:

Flux  $\sim 10^{10} \text{ sec}^{-1}$  for microfocused sources

Anode material: Cu – 8keV X-rays

Manufacturers: Rigaku, Bruker

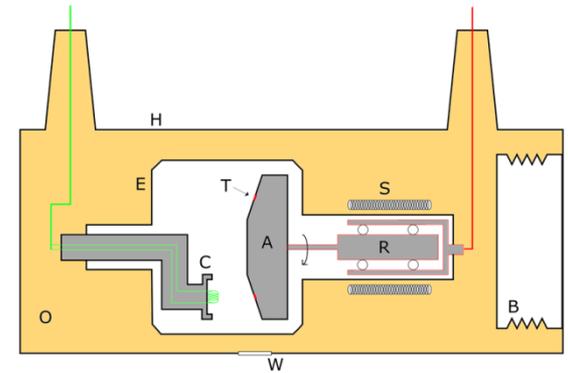

Pricy to operate (at least \$15K/yr),

Always at  $\sim 6000$  RPM,

Filaments need to be replaced often.

In the scheme, c is cathode, a anode,

w – xray window

Sealed tube source:

No moving parts,

Cheap to operate (\$2K/yr),

Last for up to 3 years.

Manufactures: Rigaku, Bruker, PANalytical, Hamamatsu

Line shaped sealed tube sources provide flux comparable to non-microfocused rotating anodes at the expense of data smearing.

## Comparison of lab sources (Source: Bruker)

	<b>Relative Brightness<sup>1</sup></b>	<b>Maintenance Requirements</b>	<b>Typical Relative Cost</b>	<b>Installation Requirements</b>	<b>Suitable Applications</b>
Conventional sealed tube	1	Low <sup>2</sup>	1	3-phase power, water cooling	Strong diffractors
Microfocus sealed tube	3-5X	Low <sup>2</sup>	2-3X	None	Strong-moderate diffractors
Conventional rotating anode (5 kW, 300 $\mu\text{m}$ )	3-10X	High <sup>3</sup>	3X	3-phase power, water cooling	Strong-moderate diffractors
Microfocus rotating anode (2 kW, 70 $\mu\text{m}$ )	20-50X	Medium <sup>4</sup>	3-4X	3-phase power, water cooling	All

<sup>1</sup> Copper  $K\alpha$

<sup>2</sup> Typically replace tube every 1-3 years

<sup>3</sup> Typically replace filament 4-6 times per year, refurbish anode annually

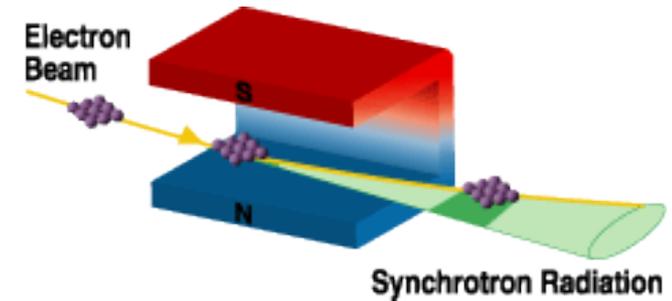

<sup>4</sup> Typically replace filament 2-3 times per year, refurbish anode annually

Where do the synchrotron X-rays come from?

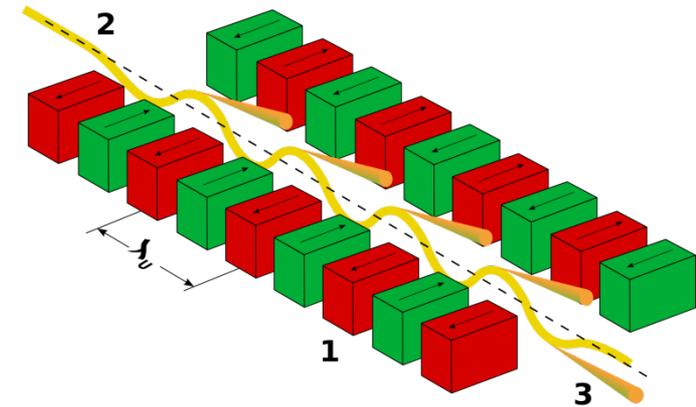

**Bending magnet:** a single dipole magnet.

Has the lowest radiation flux, energy spectrum is broad.

Used at Beam Line X33 at EMBL-Hamburg.

**Undulator:** a periodic structure of dipole magnets that create an alternating magnetic field with a wavelength  $\lambda_u$ . Electron acceleration creates an intense radiation within a narrow energy band (due to a small e- motion amplitude and the resulting interference patterns), collimated on the electron orbit plane. For N periods, radiation intensity is up to a factor of  $N^2$  higher than that of the bending magnet. Used at APS Beam Lines I8ID and I2ID.

**Wiggler:** an undulator operating in a regime with a large e- motion amplitude, creating independent contributions from each period and resulting in a broad energy spectrum.

Used at SSRL Beam Line 4-2.

**Synchrotron radiation characteristics:**

Intense, focused, coherent, polarized, tunable wavelength, delivered in short bursts.

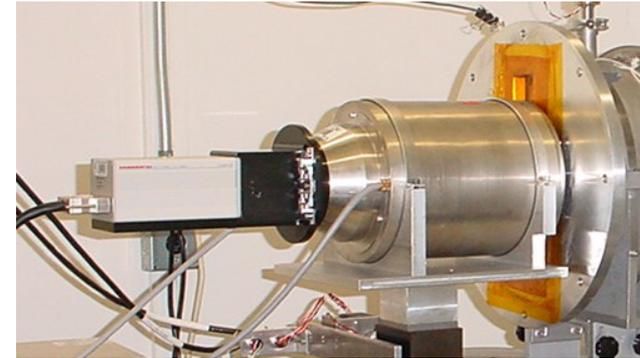

## X-ray detector types

**Multi-wire gas filled proportional detector** (Gabriel type, 1D or 2D) detects individual ionization events by X-rays of the filler gas ( $\text{CO}_2/\text{Ar}$ ). They have the lowest noise of all types, wide dynamic range limited by high local count rate, their main limitation (max  $\sim 50000/\text{sec}$  global or  $\sim 100/\text{sec}$  local). Their spatial resolution is limited ( $100\text{-}500\ \mu\text{m}$ ). They work best for lower flux sources (lab-based and synchrotrons such as SSRL).

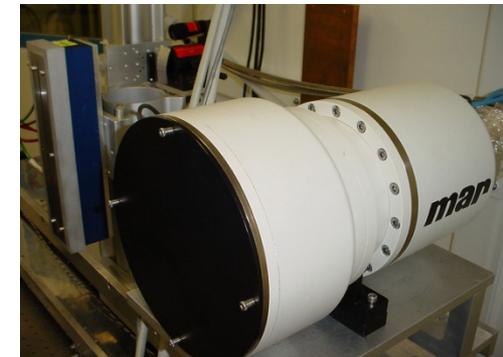

**Imaging plates** are suitable for lab-based sources. They exhibit very high linear dynamic range ( $\sim 5$  orders of magnitude) and good spatial resolution ( $50\ \mu\text{m}$ ). Not suitable for synchrotron sources.

**Image intensified CCD detectors** (Hamamatsu): high sensitivity, large area, very rapid data acquisition. Since their count rate is unlimited, they are suitable for all synchrotron sources.

**Fiber optic tape CCD detector** (Mar): unlimited count rate, small pixel size ( $50\text{-}80\ \text{mm}$ ), low image distortion, rapid data collection. Suitable for all synchrotron sources

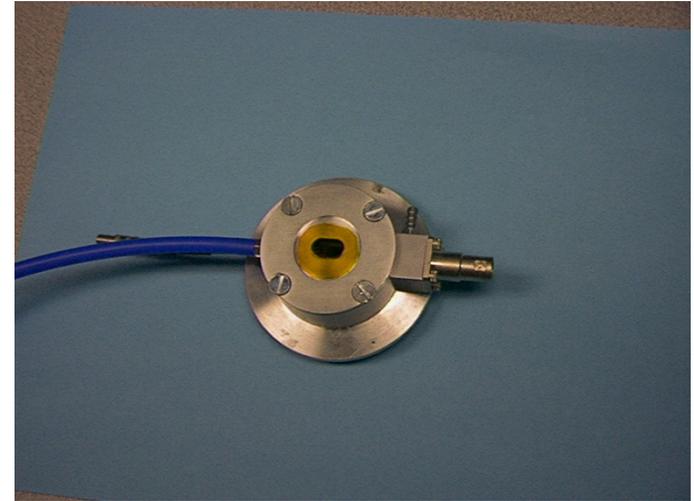

Detectors are periodically calibrated by long data collections of known profiles. This can be done with either  $^{55}\text{Fe}$  radioactive source or with scattering by a glassy carbon standard samples previously calibrated using neutron scattering.

## Count rate monitors

Accurate subtraction for the buffer scattering from the sample requires calibrations by the photon fluxes during the two measurements. This is accomplished by measuring beam intensity upstream and downstream from the sample.

The **incident intensity** (upstream) measurement is typically done with either ionization chambers or NaI scintillation detectors pointing towards a transparent scattering material (such as Kapton foil) in the beam. Ionization chamber measurements are limited by the drift of the dark current and NaI by the radiation damage/variable energy deposition to Kapton.

The **transmitted intensity** (downstream) measurement is done with a beamstop-mounted photodiode. Its accuracy is limited by the drift of the photodiode's dark current and the lateral drift of the beam during data collection. The transmitted intensity is affected by any changes in sample material including radiation damage and bubble formation.

The transmitted intensity measurement can also be done using a semi-transparent beam stop to get the transmitted beam intensity to a level comparable to the scattering

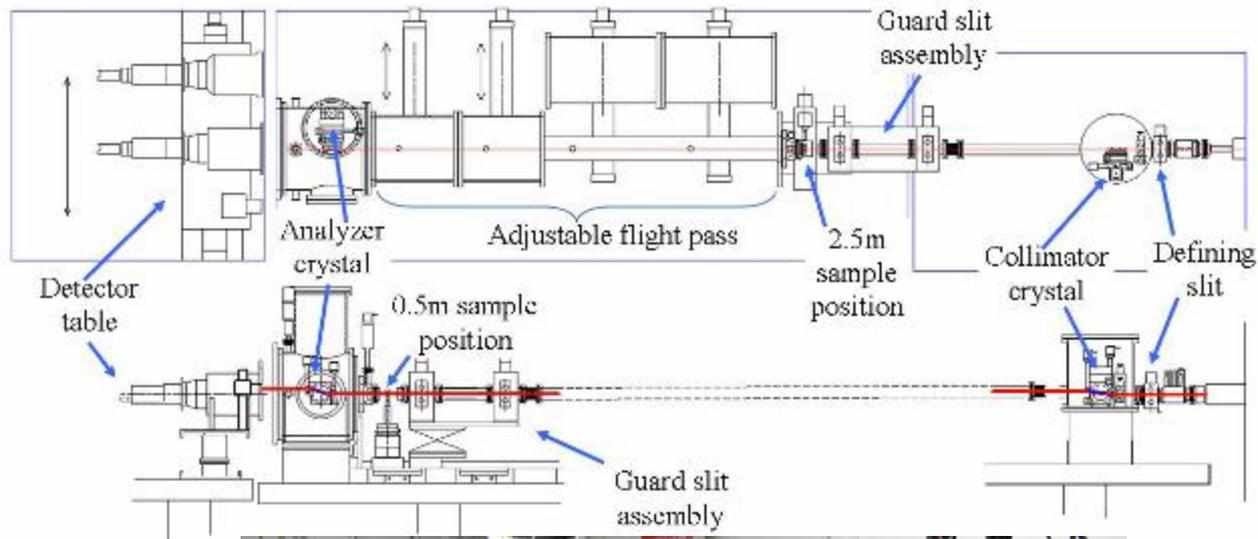

# SSRL Beam Line 4-2

Dedicated for bio-SAXS and diffraction. Source is a 20-pole wiggler magnet.

energy range: 6-14 keV  
q-range: 0.003 - 3 Å<sup>-1</sup>  
flux: ~5 10<sup>11</sup> sec<sup>-1</sup>

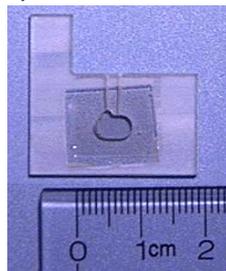

Detectors: linear gas proportional, quadrant gas proportional, Hamamatsu image-intensified CCD, Mar fiber optic taper coupled CCD, Rayonix 225HE back illuminated taper CCD

9 mo/yr operation, 3 proposal cycles

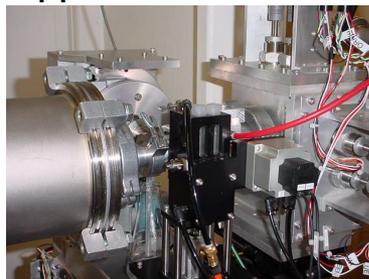

sample cells:

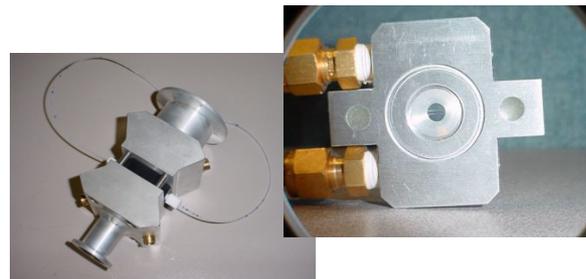

15 μL, static

stropped flow mixer

in-vacuum flow cell

# SAXS Beam Lines at APS

**I8ID (BioCAT):** dedicated for bio-SAXS and fibre diffraction.

source: APS Undulator A

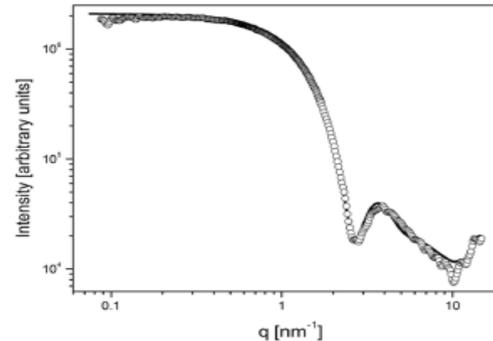

energy range: 3-13 keV (fundamental),

10-40 keV (3<sup>rd</sup> harmonic)

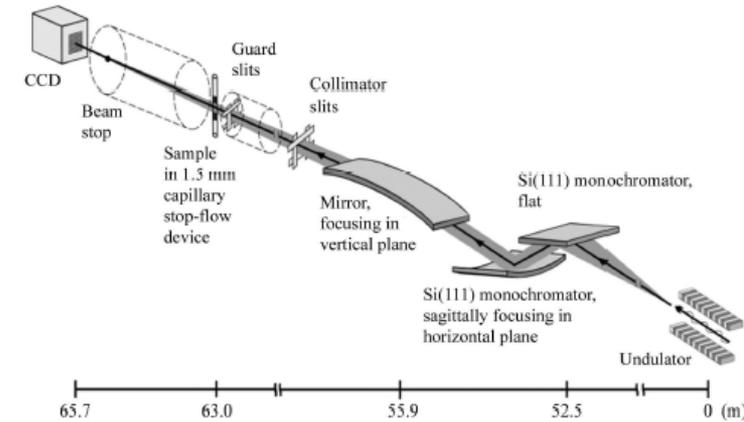

q-range: 0.003 – 2.5 Å<sup>-1</sup>

flux: ~10<sup>13</sup> sec<sup>-1</sup>

~70% of operation is user time

Final beam size: 35 μm x 135 μm

sample data above: 2.5 mg/mL cytochrome c, 1s data collection at 2m and 0.3 m

Fiscetti, F et al. (2004) The BioCAT undulator beamline I8ID: a facility for biological non-crystalline diffraction and X-ray absorption spectroscopy at the Advanced Photon Source. *J. Synchrotron Rad.* 11, 399-504

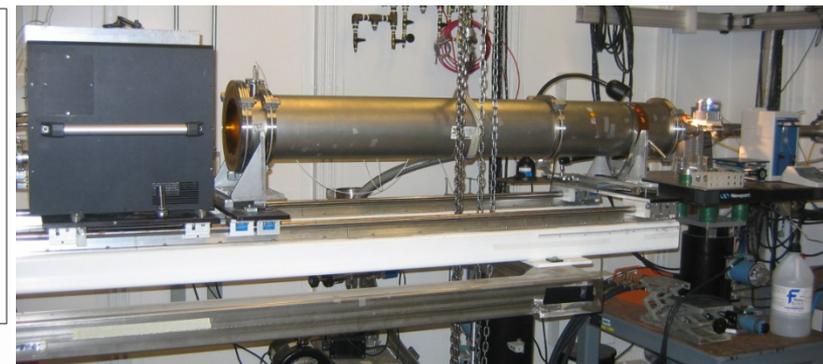

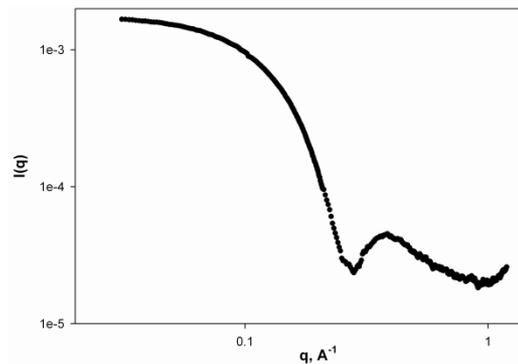

**I2ID (BESSRC):** material science, chemistry, biomolecular.

source: APS Undulator A

energy range: 3-27 keV

q-range: 0.003 – 2.5 Å<sup>-1</sup>

flux: ~10<sup>13</sup> sec<sup>-1</sup>

sample data above: 2.5 mg/mL cytochrome c, 1s data collection at 4m and 0.3 m

~70% of operation is user time (not all is for SAXS)

## **3b. Data Acquisition**

- Synchrotron-based SAXS experiments
- Bench-top X-ray source-based SAXS experiments
- Neutron scattering

## Synchrotron data collection overview

Measure empty capillary, capillary with buffer and capillary with sample along with transmissions (if possible). Best practice is to subtract empty capillary from both buffer and sample then to subtract buffer from sample. Watch for radiation damage – monitor  $P(r)$  and Guinier during data collection, attenuate beam and decrease exposure when necessary.

Measure in 2 configurations (SAXS and WAXS whenever possible), then merge. Use SAXS to evaluate low- $q$  behavior (inter-particle interference, aggregation, radiation damage) and WAXS to evaluate sample/buffer matching. Maximum exposure time with SAXS is going to be limited by low- $q$  scattering near the beam stop. For WAXS it will be limited by the water peak intensity.

Optimize exposure times to prevent both radiation damage and detector saturation. Higher solute concentrations (5-20 mg/mL) can be used for WAXS - with  $q_{\min} \sim 0.1 \text{ \AA}^{-1}$  structure factor should not be an issue. Concentrations as low as  $\sim 0.1 \text{ mg/mL}$  protein can be measured.

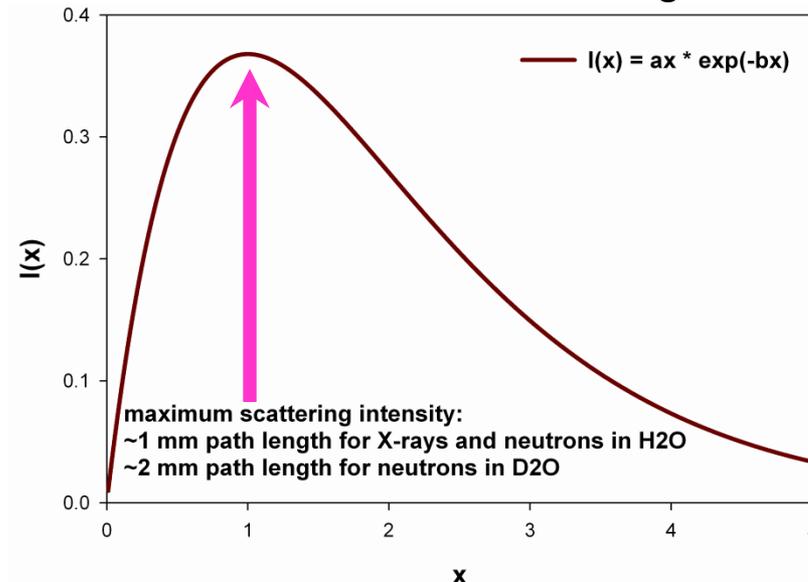

## Data collection: sample handling

Sample volumes are 15-30  $\mu\text{L}$  for a static cell and 50-150  $\mu\text{L}$  for a flow-cell.

It is best to measure buffer before and after each sample measurement to detect protein deposition on the cell walls.

Cleaning the cell between measurements is crucial. A sequence of using water / bleach / isopropanol / water works well with quartz capillaries. The final wash before any load (whether sample or buffer) should be the matching buffer.

If the sample is oscillated during data collection, dilution with droplets of buffer left by the previous wash can and will occur. The consecutive individual data frames might thus exhibit a systematic lowering of scattering intensities. This should not be confused with radiation damage. On the other hand, oscillation of the sample, typically done to decrease radiation damage, does not eliminate the laminary nature of the flow. Therefore, protein molecules close to the capillary surface are not exchanged as fast as the interior of the capillary and might still experience a radiation dose that leads to radiation damage.

Optimal path length depends on solvent absorptivity and probability of multiple scattering

## Lab-based data collection overview

Radiation damage is not an issue, but s/n is. Long data collections (hours) for capillary with buffer and sample are necessary.

Room temperature stability and bubble formation in the cell during these long data collections is the main issue determining data match quality.

If line source is used, desmearing will be necessary.

Data scaling is done relative to the transmitted intensity measurements using beamstop mounted pin diodes or semi-transparent beam stops.

Minimum concentration is  $\sim 1$  mg/mL protein.

## Line beam lab sources

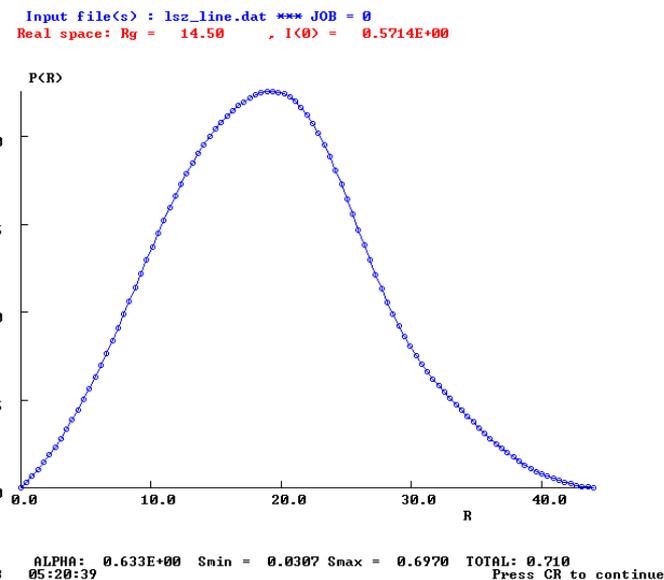

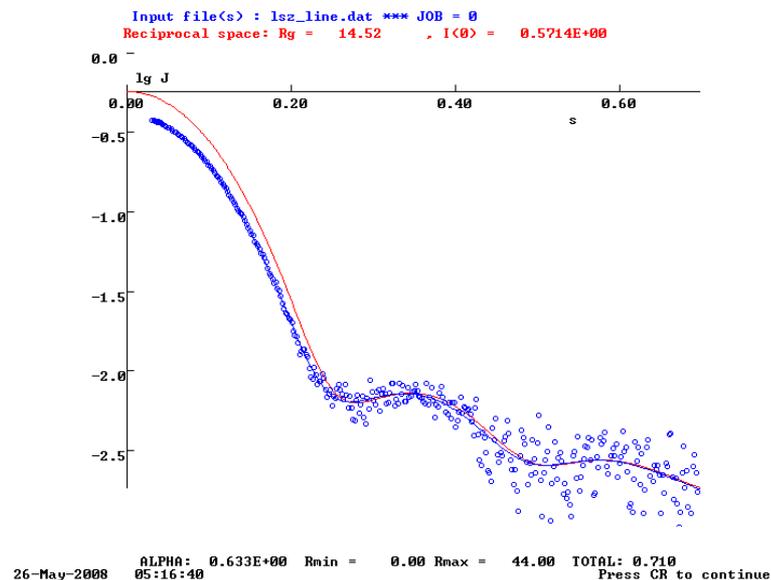

Advantage: high flux for a lab source.

Disadvantage: the need to remove the effect of the beam profile from the data (desmearing). Primarily low- $q$  data are affected.

Beam shape measurement is needed for desmearing.

$$I_{0S}(h) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} W_z(z) W_y(y) I_0[\sqrt{(h-y)^2 + z^2}] dy dz$$

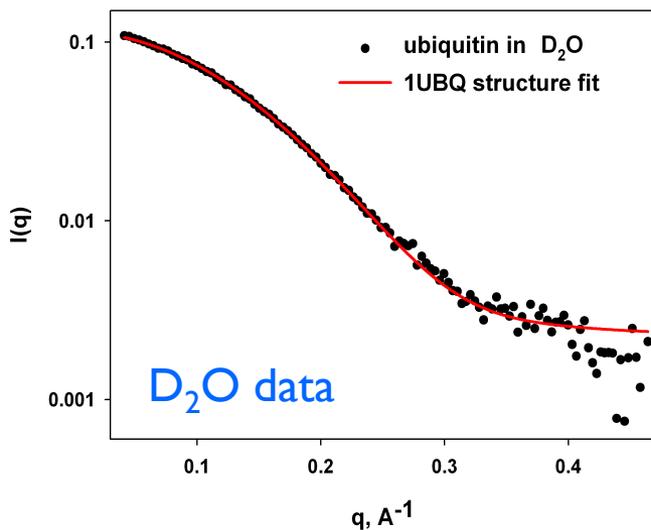

Feigin, L., Svergun, D. (1987) Structure Analysis by Small-angle X-ray and Neutron Scattering (Chapter 9). Plenum Press.

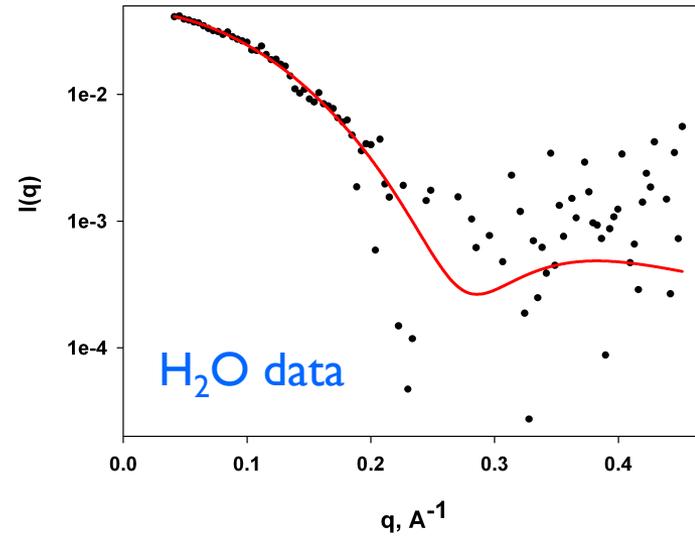

Lake, J. (1966) An iterative method for slit-correcting small-angle X-ray data. Acta Cryst. 23, 191-194.

# SANS data collection overview

- Select mean and r.m.s. neutron wavelength, exposure times, sample/detector distances and collimation parameters to cover the desired  $q$ -range with an acceptable signal/noise level. Radiation damage is not an issue for SANS!
  - Measure blocked beam, open beam, empty cell, cell with buffer and cell with sample along with the transmissions.
  - Blocked beam and empty cell are scaled by their transmissions and subtracted from all data.
  - Bubble formation and buffer evaporation during these long (hrs) measurements are main issues.
  - Minimum sample concentrations are  $\sim 2$  mg/mL protein. Low  $q$ -measurements with sample/detector distances exceeding  $\sim 5$  m require data collection times of several hrs.
  - Buffers containing more than  $\sim 50\%$   $\text{H}_2\text{O}$  also require significantly longer data collection times.
- For buffers containing more than  $50\%$   $\text{D}_2\text{O}$ , 2mm path length cell will provide significantly improved data statistics but will require  $\sim 600$   $\mu\text{L}$  sample instead of  $\sim 300$   $\mu\text{L}$  for a 1mm path length cell.

1 hr data collection on NG3 instrument for 10 mg/mL protonated protein samples

## **3c. Scattering Sample Preparation**

## Sample preparation procedure

Preparation of an exactly matching buffer is the most crucial step. Do not use the buffer the protein was dissolved in. Long (16-48 hr) dialysis works best. Hampton dialysis buttons (~ 50 uL) or Harvard Apparatus units for micro dialysis (up to 150 uL) both work very well. In cases when dialysis cannot be done (limited sample stability or limited time for prep), passing buffer by centrifugation through a proper MW-cutoff filter comes close. When doing this, be aware that the fresh membrane can have organics on it, so pass a volume of buffer to remove them first. Several cycles of buffer loading will be needed to ensure the exact match.

In order to decrease the tendency for bubble formation during data collection, the dialyzate buffer should be degassed under lab vacuum and/or sonicated.

Prior to loading the sample for dialysis, it is good to pass it through a 0.22  $\mu\text{m}$  filter.

Sample concentration should be measured after the dialysis ( $\text{OD}_{280}$  for most proteins,  $\text{OD}_{260}$  for DNA).

When transporting the sample for data collection the sample should be kept air-tight to prevent solvent evaporation especially if sample volume is small.

When preparing the buffer for a synchrotron data collection, at least 50 mL of buffer will be needed since washing the flow cell (if it is going to be used) requires a lot of volume.

## Composition of the buffer

**Salts** are often useful to suppress long-range electrostatic interactions between solutes (structure factor). They also increase background and decrease solute/solvent contrast but these effects are often negligible up to ~500 mM salt. High-Z elements should be avoided in the buffer. They decrease contrast and promote radiation damage by increasing photo-electron production. Due to RNA/DNA's higher surface charge relative to proteins, structure factor suppression by salts is usually weaker than for proteins at a given salt concentration.

**Free radical scavengers** should be included in the buffer when preparing for a synchrotron data collection as they help to minimize the radiation damage. Common choices are DTT (2-10 mM), TCEP (1-2 mM), or glycerol (~5%). In cases when these cannot be used, organic buffers containing TRIS or HEPES can also act as radical scavengers. When using DTT, keep in mind that it is oxidized by air. Degassing the dialysis buffer and keeping both sample and buffer under nitrogen throughout the entire preparation up till data collection will suppress this.

**Detergents** are best avoided unless absolutely necessary (membrane proteins). Their signal can be comparable to or exceeding the protein signal complicating data interpretation.

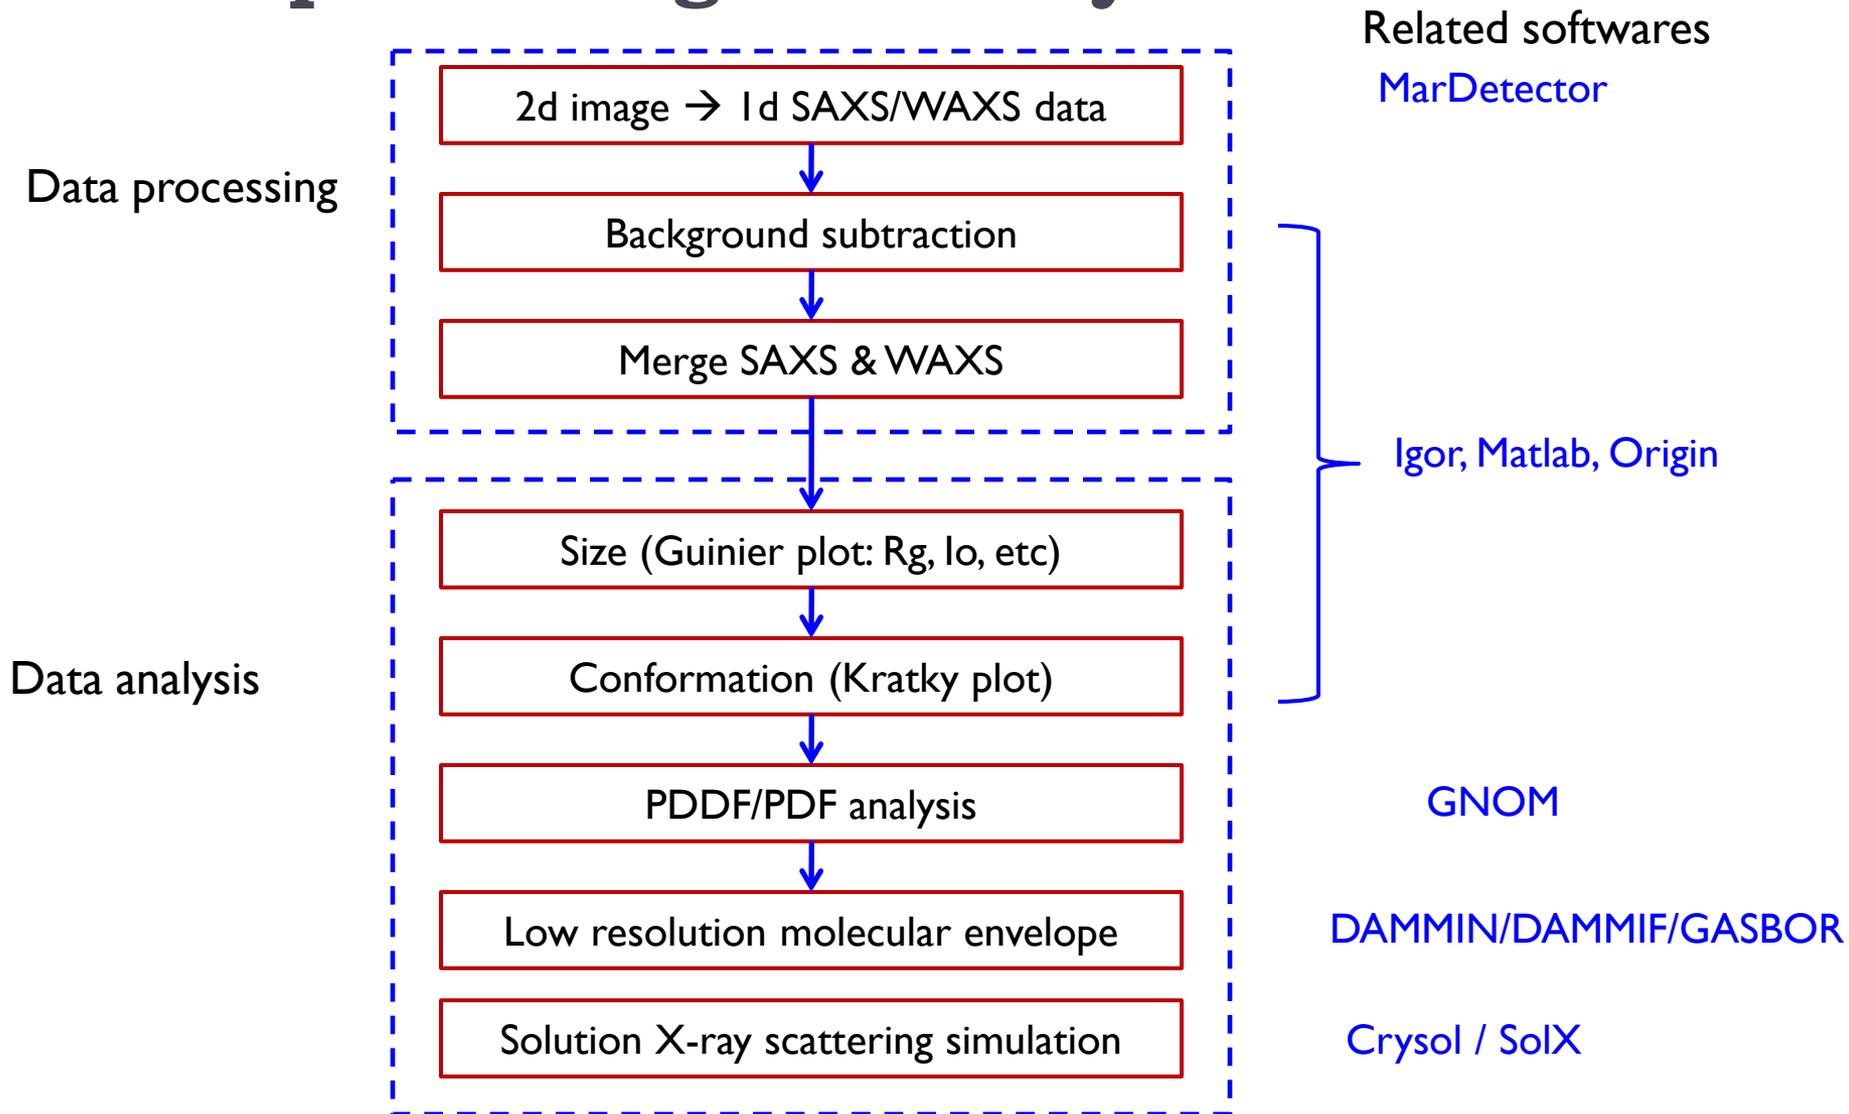

## Sample preparation issues

**Aggregation** is the most common problem that can render data uninterpretable. Up to 5% of dimer relative to the monomer in question might not affect the data too much but higher levels will. DLS or analytical ultracentrifugation can be used to detect aggregation/polydispersity and native gel (single band is required), gel filtration, or centrifugation through high-MW cutoff membrane can help to remove it.

Otherwise, sample conditions will have to be optimized. Fresh preps kept at low concentration till data collection (when they can be concentrated) work best in difficult cases. Freezing/thawing cycles can promote aggregation and are best avoided. Cryo-protectants (5-10% glycerol) can help in cases when freezing the samples is unavoidable. A fraction of very large aggregates (relative to the particle that is being studied) is better than a dimer/trimer/tetramer/etc continuum. In the former case, the scattering from aggregates can be removed by removing lowest- $q$  data. In the latter case, the entire scattering curve is affected and data become truly uninterpretable.

**Solute concentration:** On one hand, higher concentration = better signal. On the other, it can bring increased aggregation or pronounced inter-particle repulsion (or both). For proteins with  $MW < 200$  kDa 1-10 mg/mL is a suitable range. For larger proteins concentrations below 2 mg/mL should be used. A 3-6 point concentration series (such as 1, 2, 5, 10 mg/mL) should be acquired to test concentration dependence of the signal. Analysis of  $I(0)/c$  should indicate whether concentration effects are present. In those cases, zero-concentration extrapolation should be performed. For proteins in 150 mM salt buffer, structure factor is often quite small up to 8-10 mg/mL. Since RNA scattering is stronger, concentration can be lowered by a factor of  $\sim 5$  relative to proteins for a comparable  $s/n$ . When using 150 mM salt buffer, structure factor often becomes close to negligible at 1 mg/mL DNA/RNA or lower. Higher concentrations are very likely to have noticeable structure factor effects at these conditions.  $OD_{280}$  is the preferred method for measuring the concentration for proteins. When doing so, be aware that oxidized DTT will also absorb at this wavelength.

# Data processing and analysis flow chart

## **4. Data processing**

- a. 2D  $\rightarrow$  1D data conversion
- b. Background subtraction
- c. Data quality evaluation

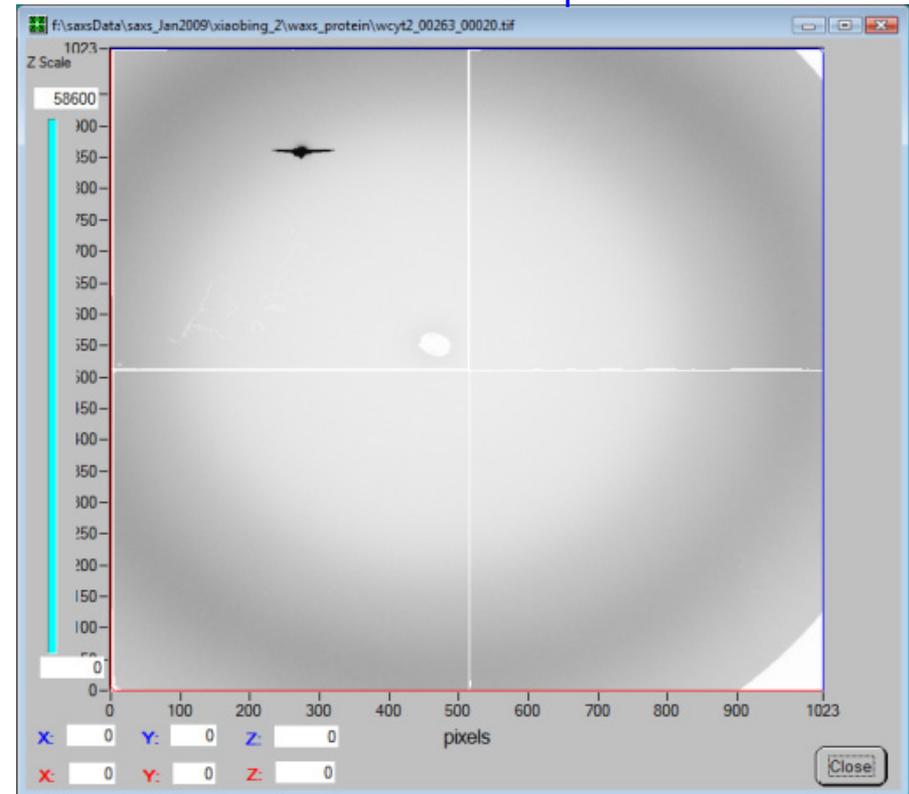

# a. 2D image $\rightarrow$ 1D data conversion

Software: Mardetector v4.9  
screen capture

1. Find beam center
2. q calibration/mapping
3. Image mask
4. Conversion

The above procedures for  
both SAXS & WAXS

done at synchrotron  
beamline station during data  
acquisition

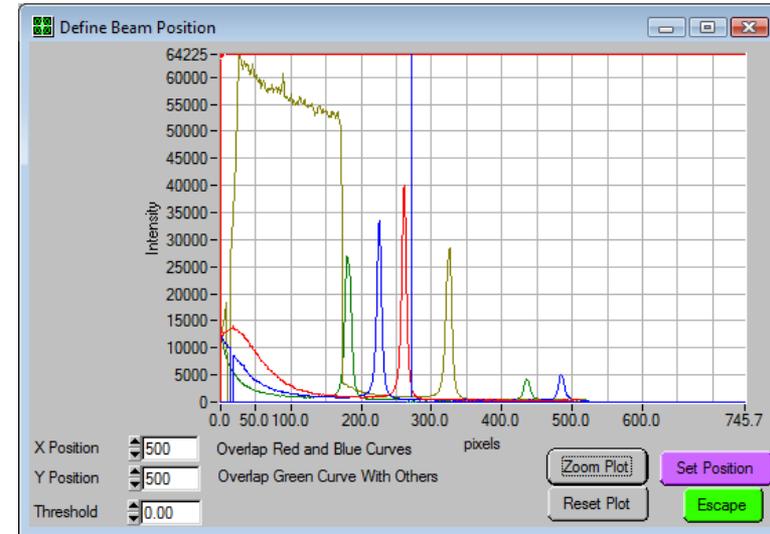

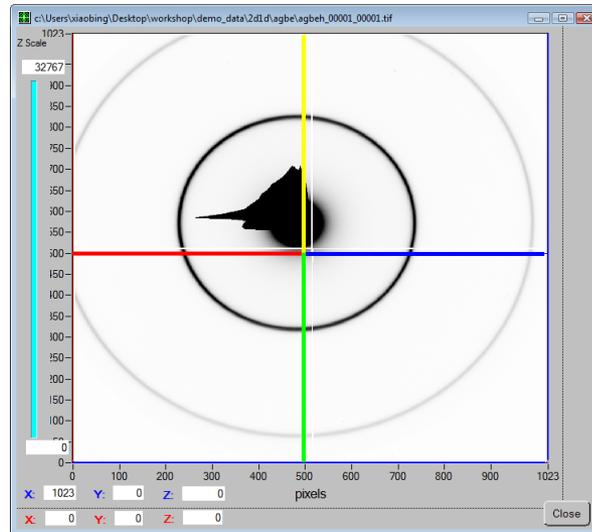

A 2D scattering image for a solution sample recorded on a home-made 2x2 CCD chips detector (gold detector) at I2-ID at Argonne

# Find beam center

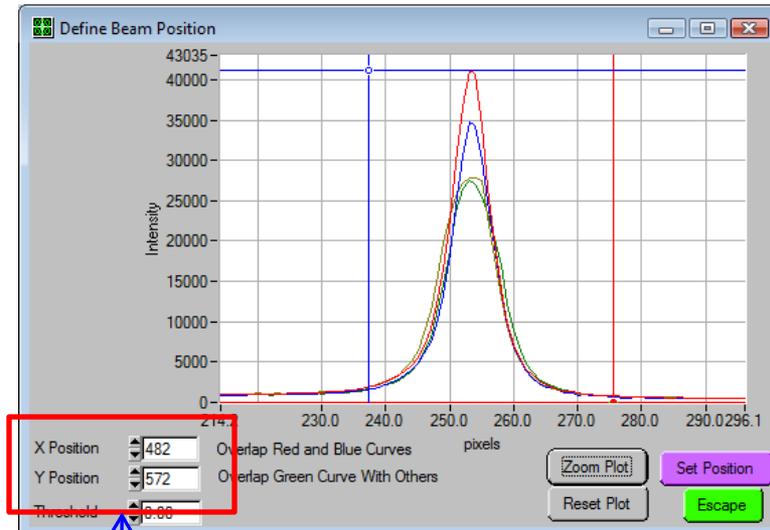

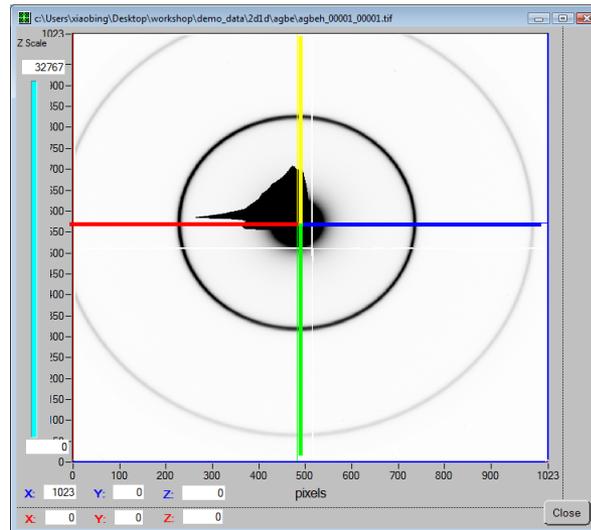

Initial: off  
beam center

Along the four  
directions, peak  
positions do not  
overlap well

At beam  
center

Peak positions  
overlap well

Scattering image  
of silver behenate

position of beam center  
on detector

# q-calibrants and sample-to-detector distance

Primary q-calibrant standards in X-ray scattering:

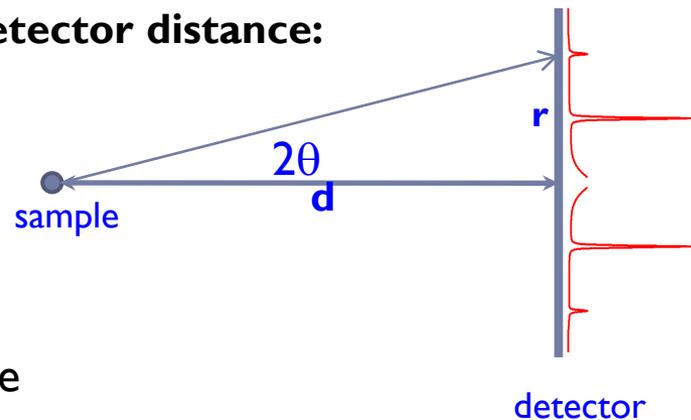

standards	d-spacing (Å)	First harmonic peak (Å <sup>-1</sup> )
Silver behenate (IUCr standard, most popular)	58.380	0.1076 0.1076 × N (N ≤ 10, Nth peak)
Cholesterol Myristate	51.1	0.1230
Wet Rat Tail Collagen	650-670	~0.01
Anatase (TiO <sub>2</sub> )	3.51	1.790

Using q-calibrant to determine sample-to-detector distance:

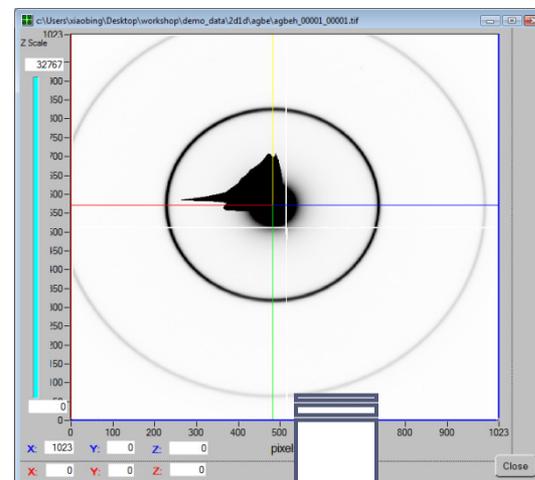

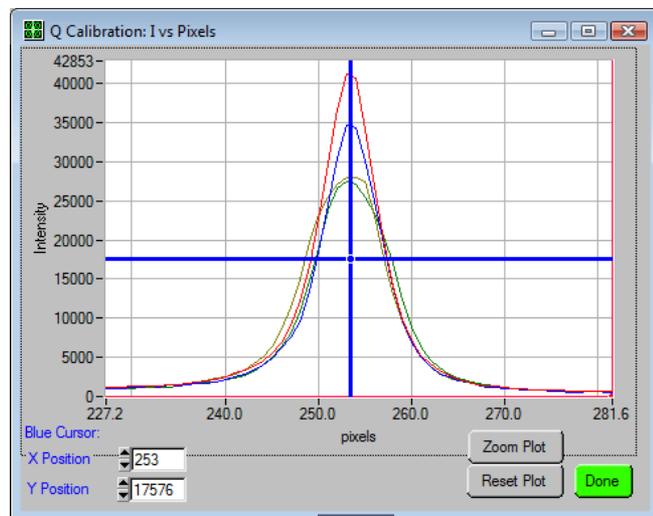

$$q = (4\pi / \lambda) \sin \theta$$

$$2\theta = \text{atan}(r / d)$$

d: sample-to-detector distance

# q value calibration/mapping

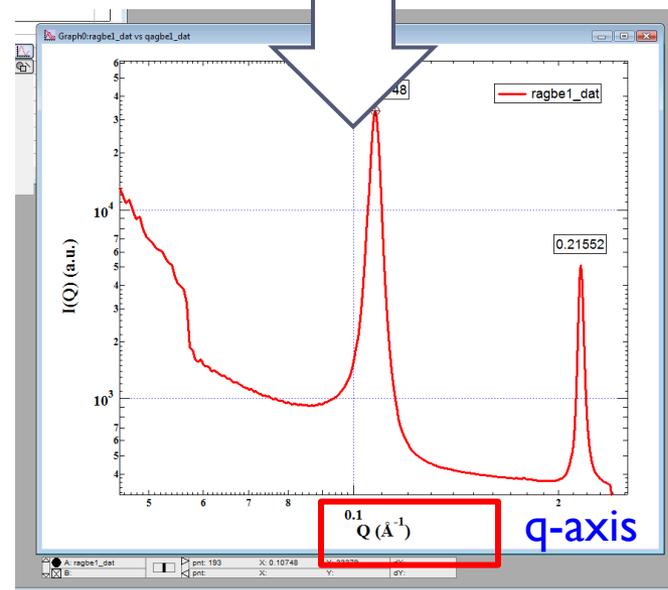

A dialog box titled "Q-Calibration" with the following fields and values:

- To Calibrate Q, Enter These Values:
- Peak Pixel Number: 253
- Q value: 0.1076
- Energy (keV): 18.000
- Lambda: 0.6888
- if pixel size = 1.0, distances in pixel units:
- pixel size (mm): 1.00E+0
- ed-Detector (mm): 2.14E+4
- Q max: 0.00000
- Calibrate Q button

Sample-to-detector distance

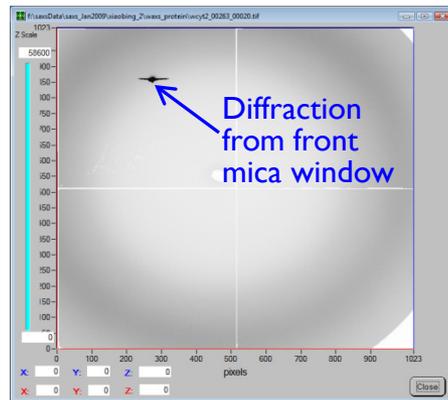

Every time sample-to-detector distance is changed, q-mapping need to redo.

# Image Mask and zinger removal

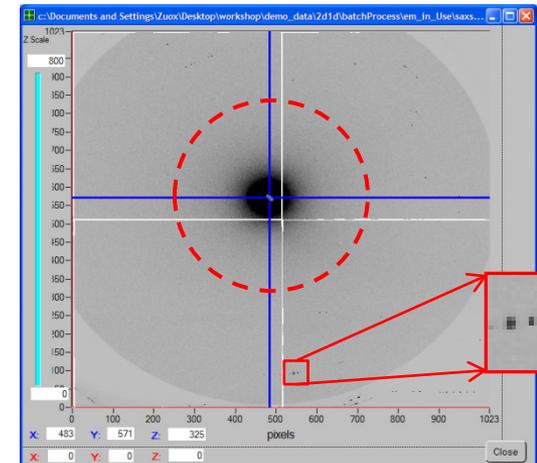

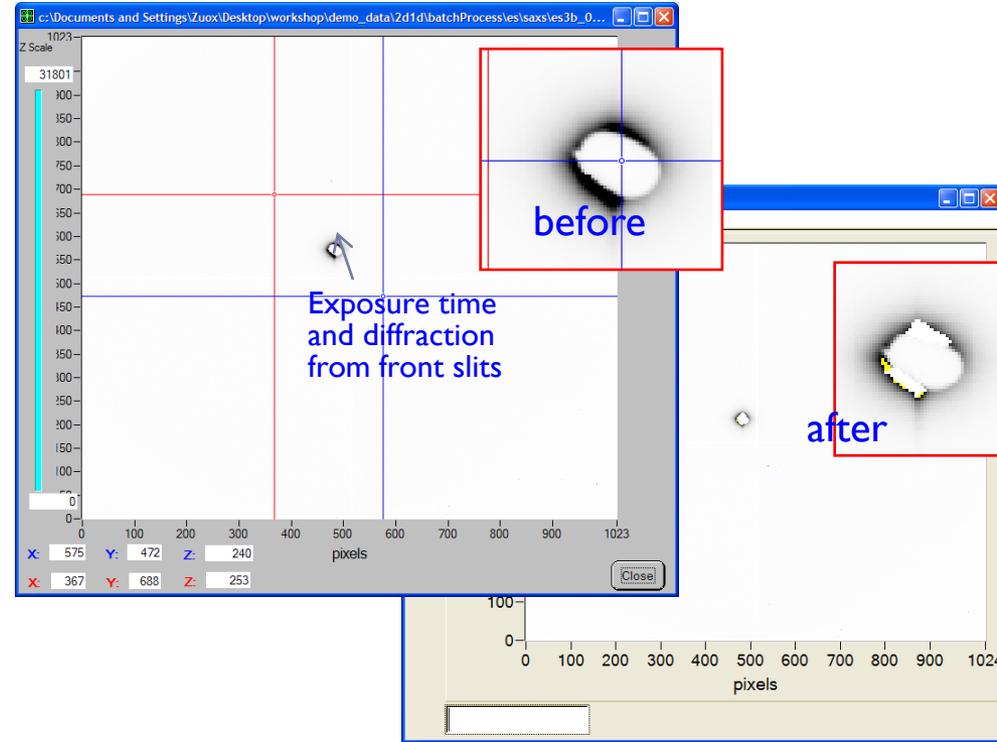

## Mask:

- detector responses nonlinearly beyond a threshold,
  - Gold detector at I2-ID: 44k
  - Marccd165: 65k
- High intensity at low q could be due to too long exposure time, diffraction from slits, fluorescence from beam stop, etc
- High intensity spots at higher q could come from diffraction of front mica window
- Mask out nonlinear pixels

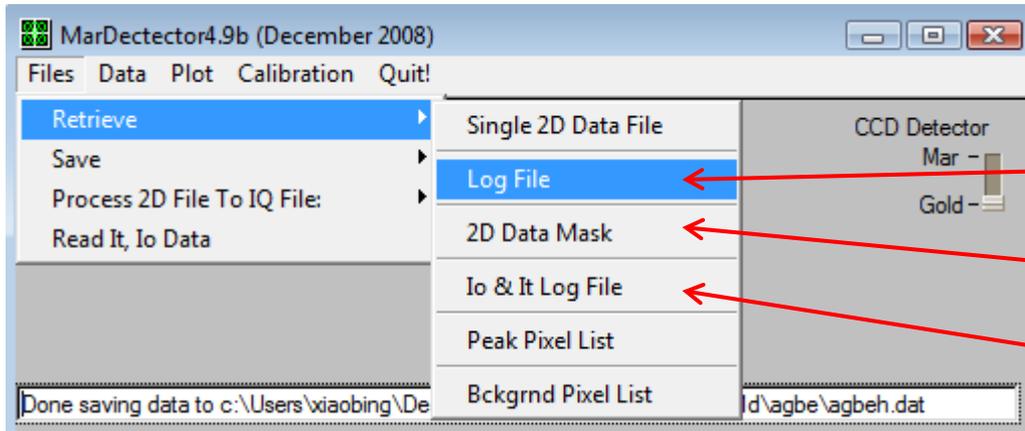

## Zinger removal:

- Zinger: spots with intensity much higher than those of neighbor pixels
- Comes from diffractions, electronic noises, etc
- ignored if  $|I(x,y) - I_{ave}| > 6\sigma$

# Softwares for data evaluation and manipulation

## Primus: developed in Svergun group

- basic data manipulation functions (averaging, background subtraction, merging of data measured in different angular ranges, extrapolation to zero sample concentration, etc.) and computes invariants from Guinier and Porod plots.
- Link other programs developed in Svergun group, such as GNOM, DAMMIN etc.

## Igor / Origin / matlab:

- Procedures / scripts available. Some of Igor procedures were copied or modified from those written by Argonne groups.
- Basic data manipulations: averaging, background subtraction, merging data, Guinier plot, Kratky plot, data extrapolation, data point sparsing
- Save parameters used in data processing

# Data manipulation Procedures in Igor

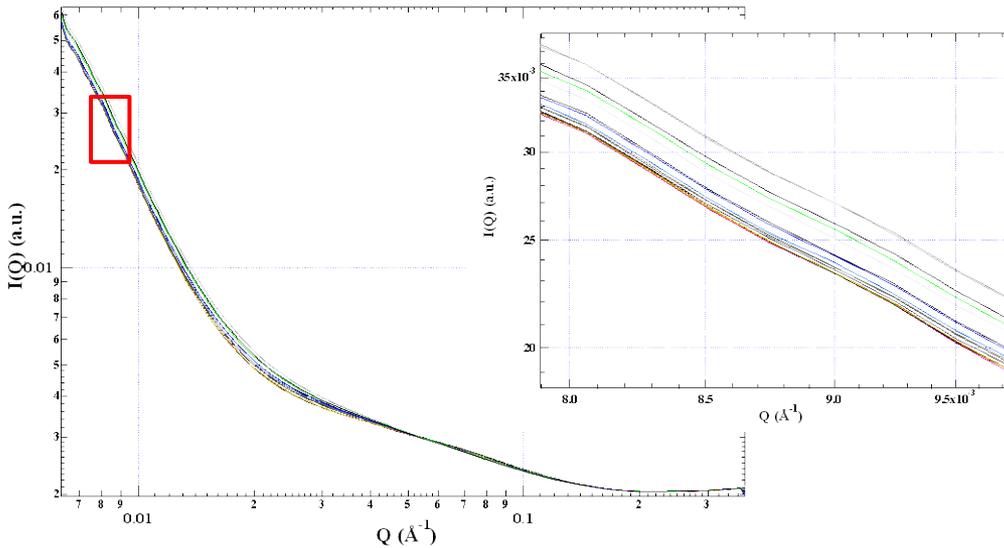

The screenshot shows the Igor Pro software interface with a menu open. The menu items are:

- Save as Text File
- Merge Data Sets
- Add To Log Log Plot...
- NCI Load ESY Files
- NCI LogLogPlot...
- NCI Subtract Background Wave.
- Average Data Sets from Plot...
- Make Guinier Plot
- Perform Guinier Fit
- Make Kratky Plot
- Remove Data Sets from Plot
- NCI Subtract Background and Cell Wave
- Subtract Background Wave and Constant, then Match

Annotations with blue arrows:

- Merge SAXS & WAXS** points to "Merge Data Sets".
- Display data** points to "Add To Log Log Plot...".
- load data** points to "NCI Load ESY Files".
- Background subtraction** points to "NCI Subtract Background Wave.", "NCI Subtract Background and Cell Wave", and "Subtract Background Wave and Constant, then Match".

# Check data convergence/reproducibility

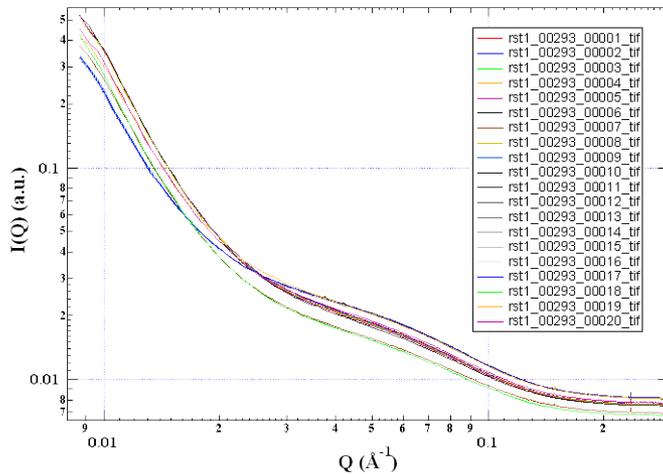

When sample degrades in X-ray, its scattering intensities change along time:

- Decrease if x-ray breaks molecules
- Increase if inducing aggregation

Real time action:

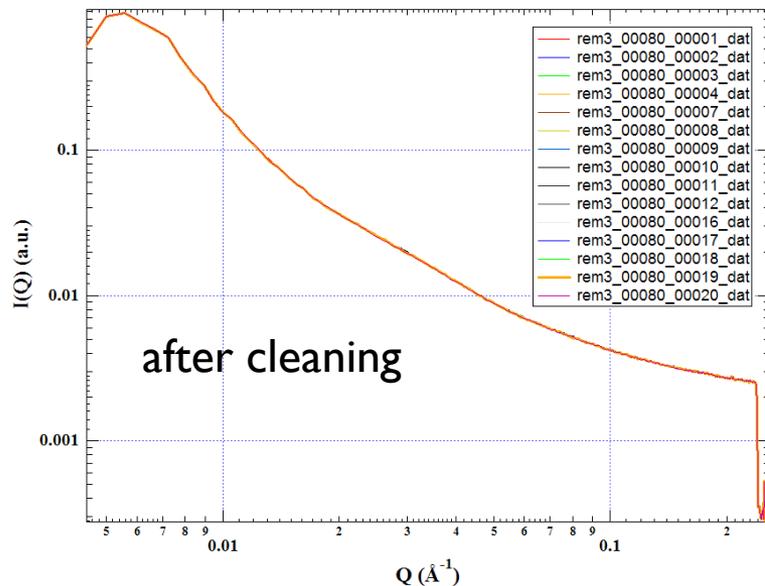

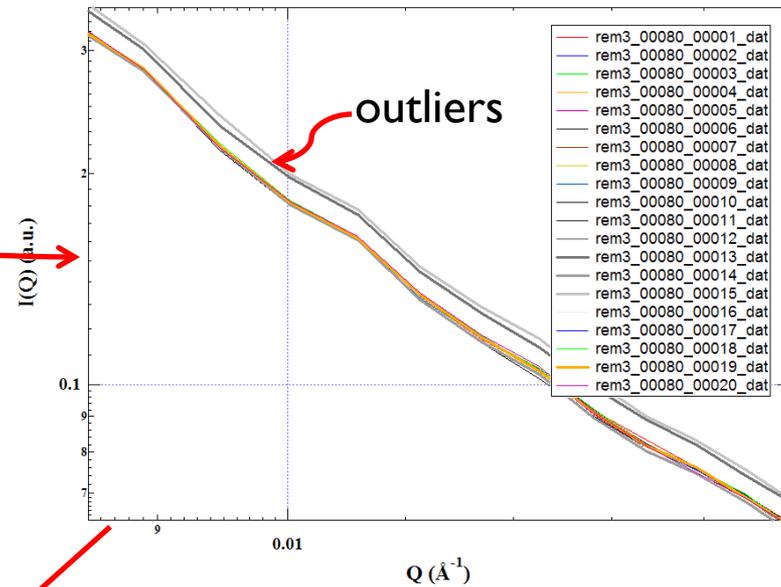

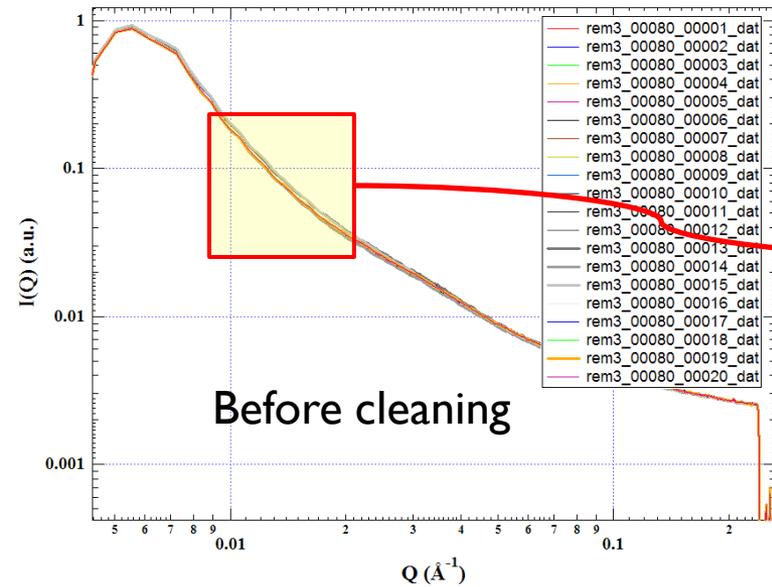

- Attenuate beam intensity/ decrease exposure time
- Increasing flow rate
- Change buffer composition if possible

Protein samples are very easy to form bubbles, therefore, scattering data may jump everywhere and become unusable.

To prevent or alleviate this problem, clean the flow cell extensively and use slower pump speeds. Or stop flow if the sample can tolerate X-ray radiation damage.

# Data cleaning and averaging

- 10-30 frames of scattering images are often collected for each sample to get good statistics.
- Outliers could exist due to air bubble, small particles, beam instability, and some unknown reasons. Outliers appear more often in sample data than in solvent/buffer data.
- Zoom in, check outliers and remove them.

# b. Background subtraction

## ▶ SAXS background subtraction:

▶ A.  $I_{\text{sample}} = I_{\text{solution}} - I_{\text{buffer}}$

Scattering intensities normalized against incident beam photon counts (I<sub>0</sub>)

- ▶ The following factors make the coefficient before  $I_{\text{buffer}}$  close but not exactly be unit: experimental errors in measuring incident photon counts, different x-ray transmission of solution vs buffer, etc

▶ B.  $I_{\text{sample}} = I_{\text{solution}} - \alpha * I_{\text{buffer}}$

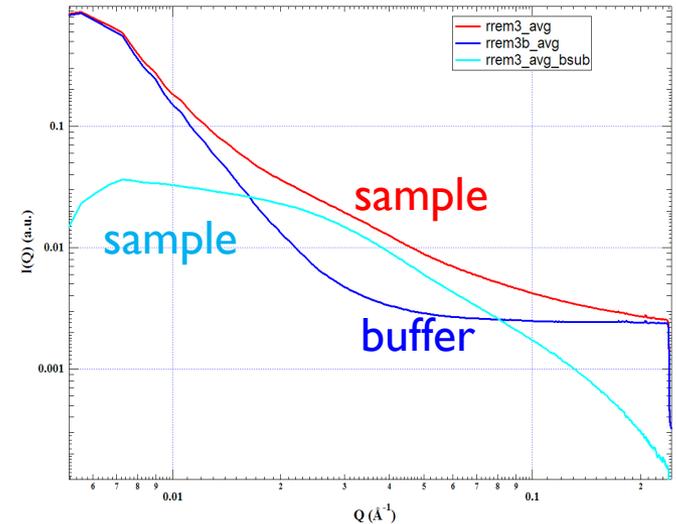

▶ protein:  $\alpha = 1 - C_{\text{mg/ml}} * 0.743 / 1000$

Nucleic Acids:  $\alpha = 1 - C_{\text{mg/ml}} * 0.54 / 1000$

Widely used in literature

▶ C. using WAXS as guide

At synchrotron beamline station, using A or B to quickly get scattering data from your molecule and do real-time data evaluation.

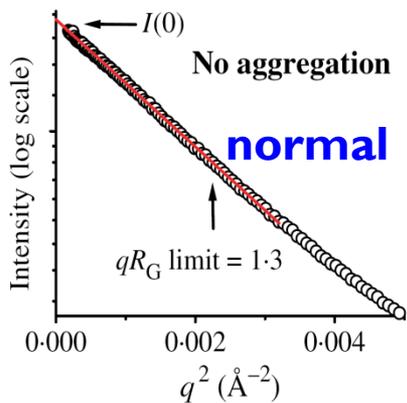

A screenshot of the 'NCISubtractBackgroundWave' software interface. The window title is 'NCISubtractBackgroundWave'. It contains three input fields: 'Enter Background Data Wave:' with a dropdown menu showing 'buffer' and 'rem3b\_avg'; 'Enter the Scale Factor for This Background Data:' with a text input field containing '1' and a label ' $\alpha$ '; and 'Enter Data Wave:' with a dropdown menu showing 'sample' and 'rem3\_avg'. At the bottom, there are three buttons: 'Quit Macro', 'Continue', and 'Help'.

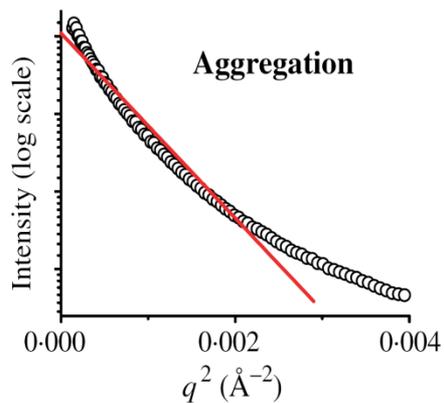

# SAXS data evaluation

Guinier equation:  
 $q \rightarrow 0$

$$\ln[I(q)] = \ln[I(0)] - R_g^2 q^2 / 3$$

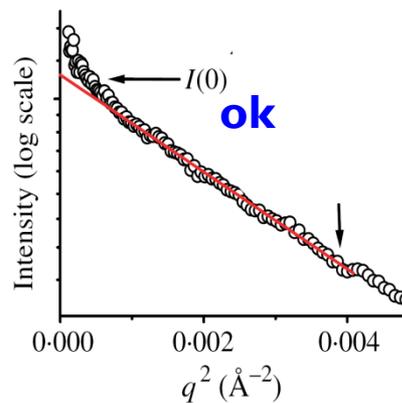

Mono-dispersed sample

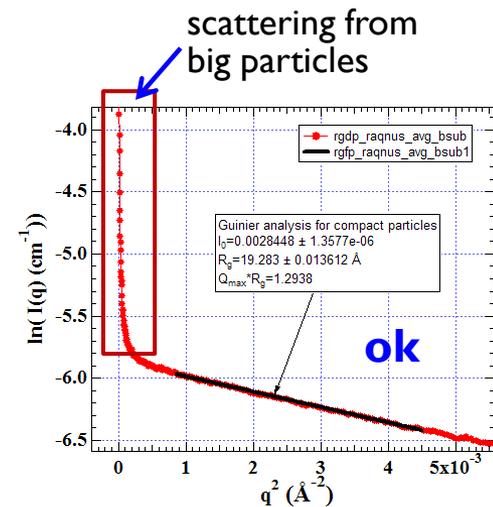

polydispersed (continuous size distribution) sample

Need to re-condition  
 Data unusable

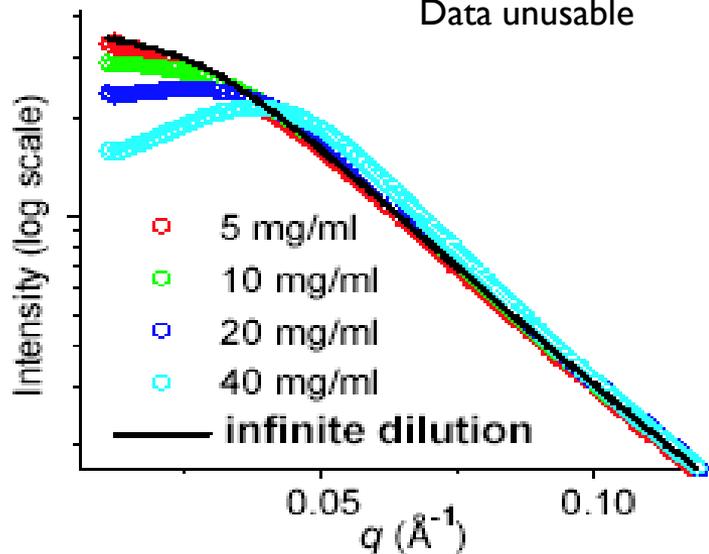

With small amount of aggregation

Data fixable

sample with big particles  
 Scattering from big particles:  
 huge slope, drop fast  
 To remove: 0.22 $\mu$ m filter

- Repulsive electrostatic interactions among molecules
- Add salt to shield the interactions
- Structure factor often less obvious for dilute sample and higher salt solution
- Do a series of concentration
- Intensity extrapolation to with 0 structure factor

# WAXS background subtraction

## Why WAXS?

- Wider q range
- WAXS data is good guide for SAXS data subtraction

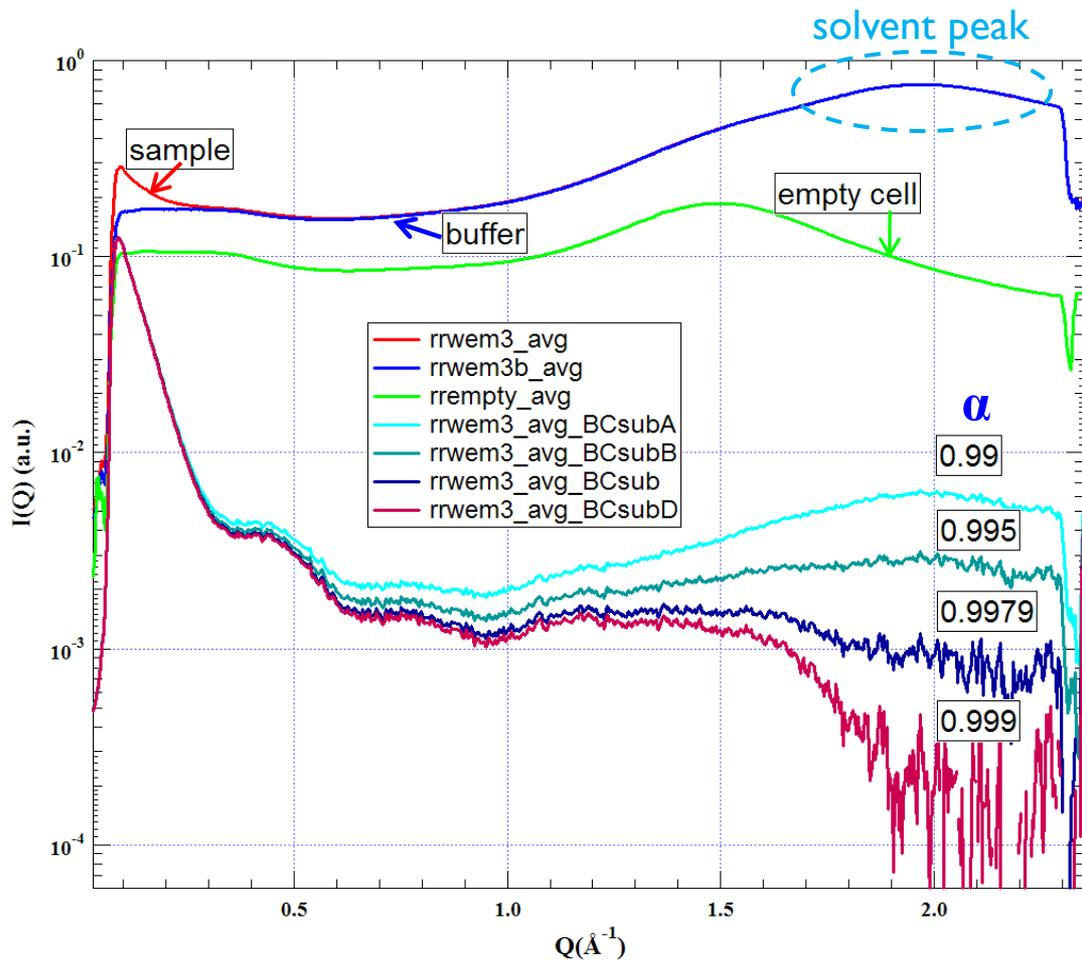

The total scattering from the sample solution comprises of those from biomolecules, buffer, and x-ray cell.

$$I_{\text{molecule}} = I_{\text{solution}} - \alpha I_{\text{buffer}} - (1-\alpha) I_{\text{empty\_cell}}$$

All Intensities have been normalized vs I<sub>0</sub>

Residual empty cell scattering becomes significant only for dilute samples

Watch the solvent peak (at ~2.0 Å<sup>-1</sup>) disappear

- under-subtraction (significant amount solvent)
- reasonable subtraction
- over-subtraction Derivative type shape

# WAXS data guided SAXS background subtraction

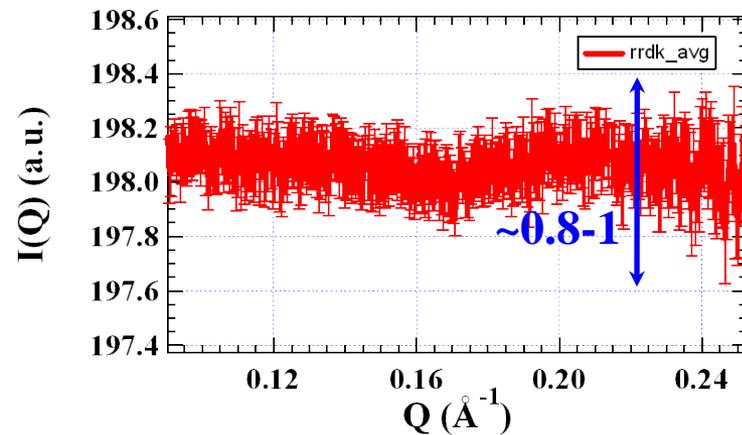

## How to?

(1). SAXS:  $I_{\text{sample}} = I_{\text{solution}} - \alpha * I_{\text{buffer}} - \text{const}$

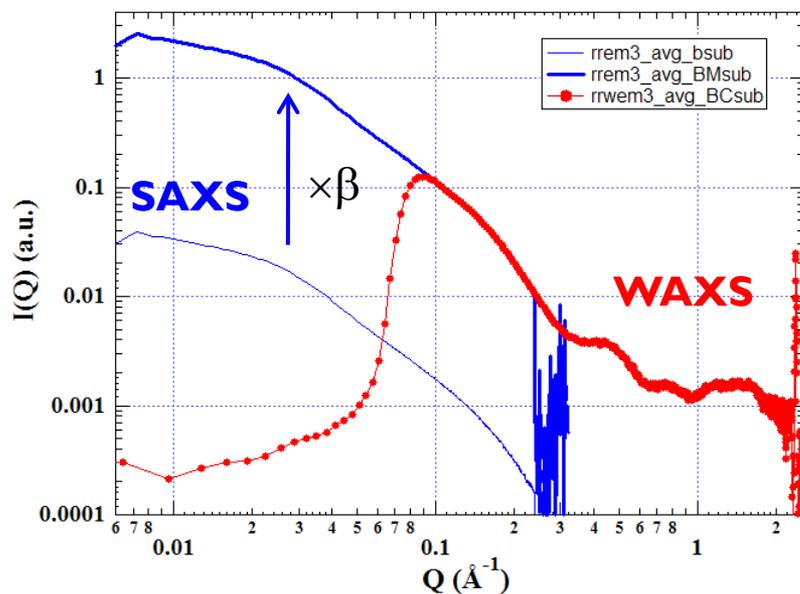

$\alpha$ : account for contribution from buffer  
 const: q-independent residual electronic noise and drift

(2). Match  $I^{\text{waxs}}$  and  $\beta I^{\text{saxs}}$  at overlapping q ranges:

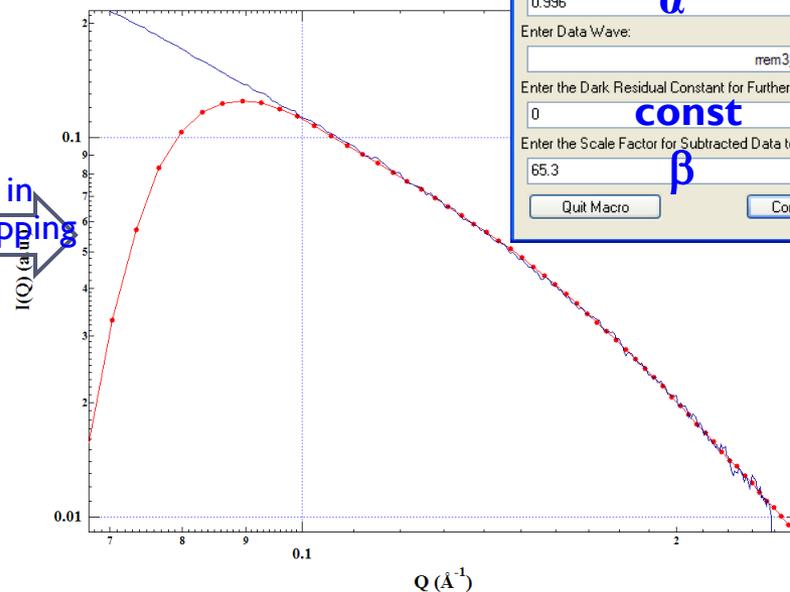

(3). Interactively tune  $\alpha$  (**const** if necessary) and  $\beta$  to make SAXS and WAXS have best match.

Average of 10 dark (no x-ray) images.  
 Residual electronic noise (**const**) should not exceed  $\sim 2^{0.5} \times 1/I_0 \approx 2.7e-5$

Zoom in overlapping region

NCISubtractBackgroundWaveMatch

Enter Background Data Wave:

Enter the Scale Factor for This Background Data:

 **const**

Enter the Scale Factor for Subtracted Data to Match WAXS:  
 **β**

# SAXS background subtraction

- ▶ SAXS background subtraction:

- ▶ A.  $I_{\text{sample}} = I_{\text{solution}} - I_{\text{buffer}}$

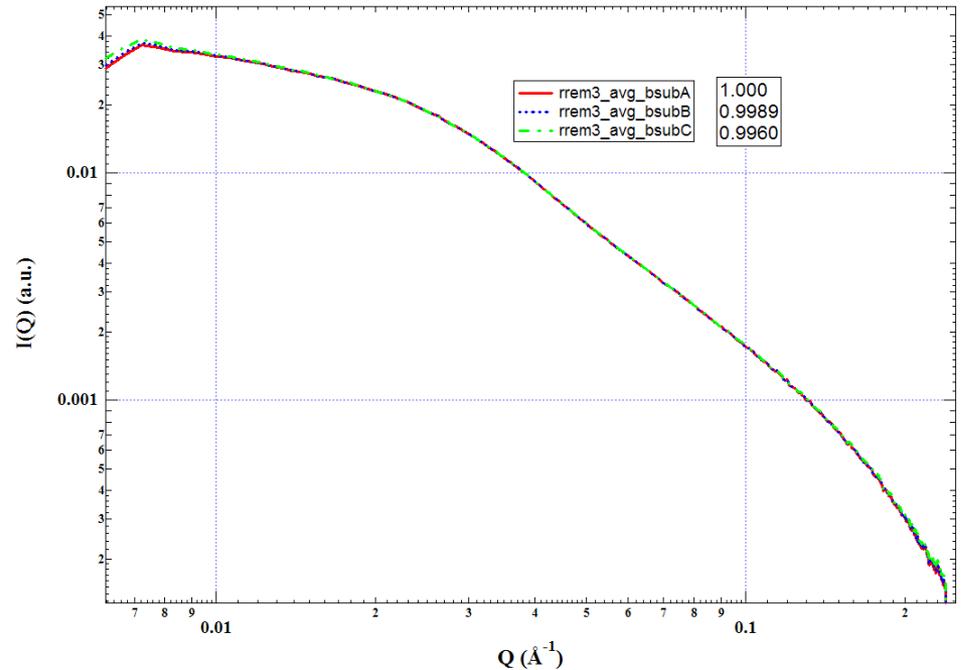

- ▶ B.  $I_{\text{sample}} = I_{\text{solution}} - \alpha * I_{\text{buffer}}$

- ▶ protein:  $\alpha = 1 - C_{\text{mg/ml}} * 0.743/1000$

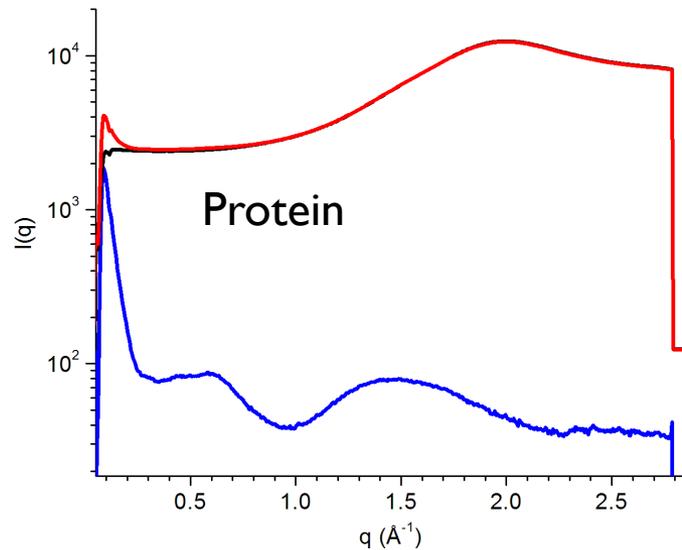

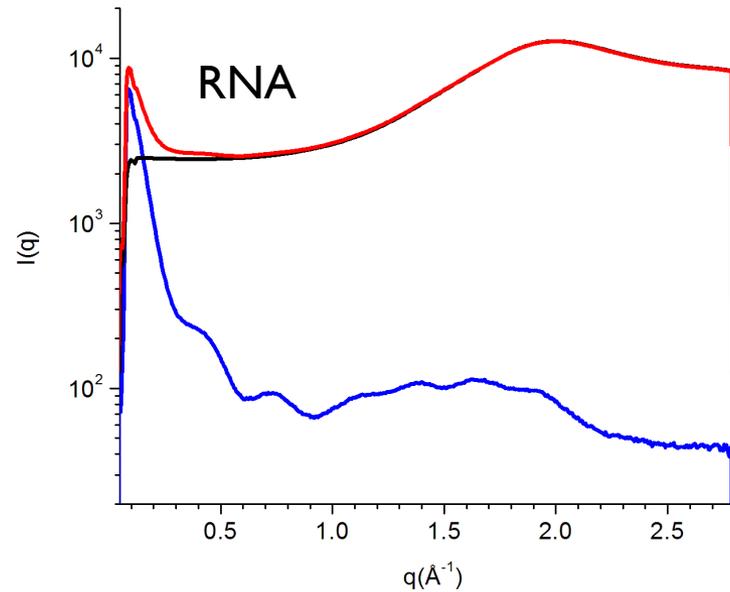

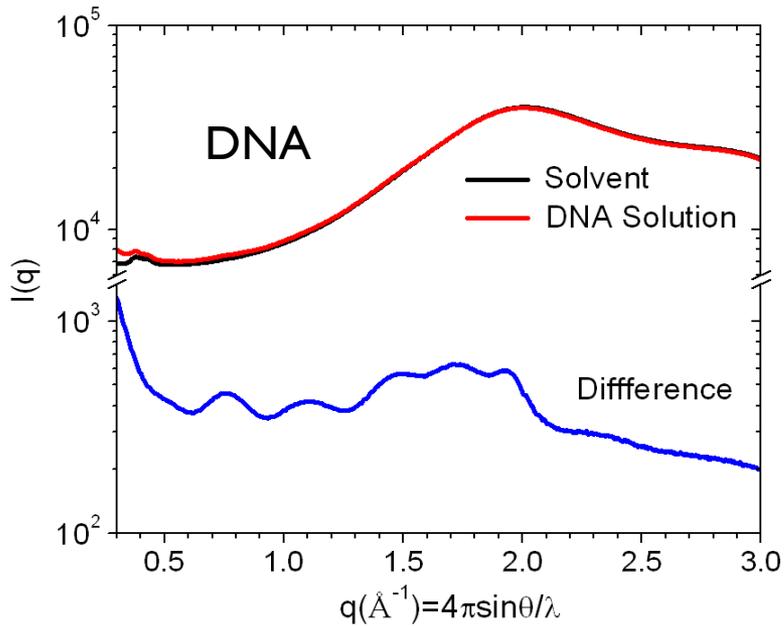

- ▶ Nucleic Acids:  $\alpha = 1 - C_{\text{mg/ml}} * 0.54/1000$

- ▶ C. using WAXS as guide

- The difference in Guinier region is often small, biggest difference often appears at the high q end, i.e., the slope at high q end.
- For this sample, SAXS data from three subtractions are very close.

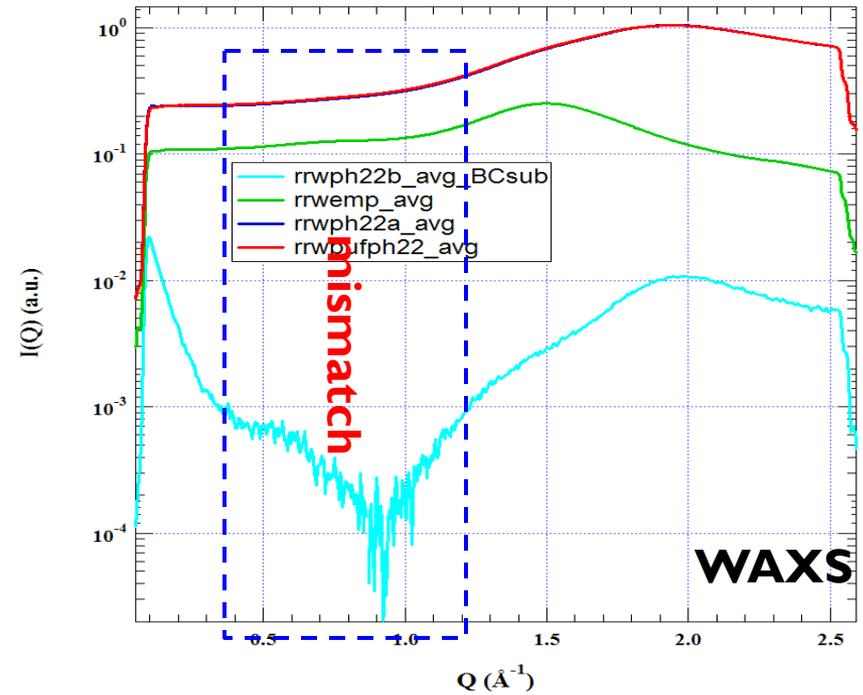

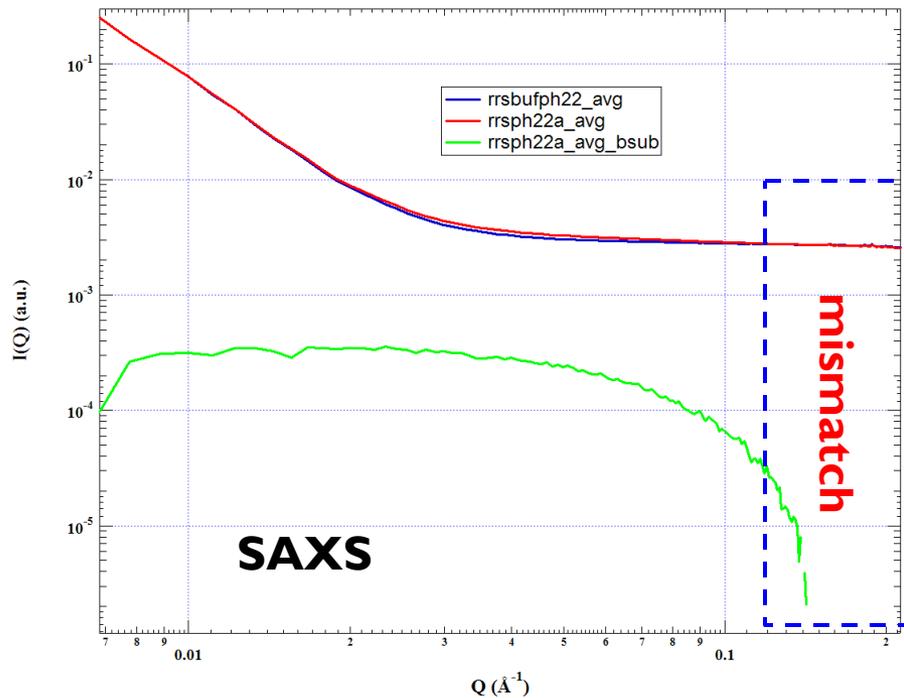

# Some good WAXS background subtraction

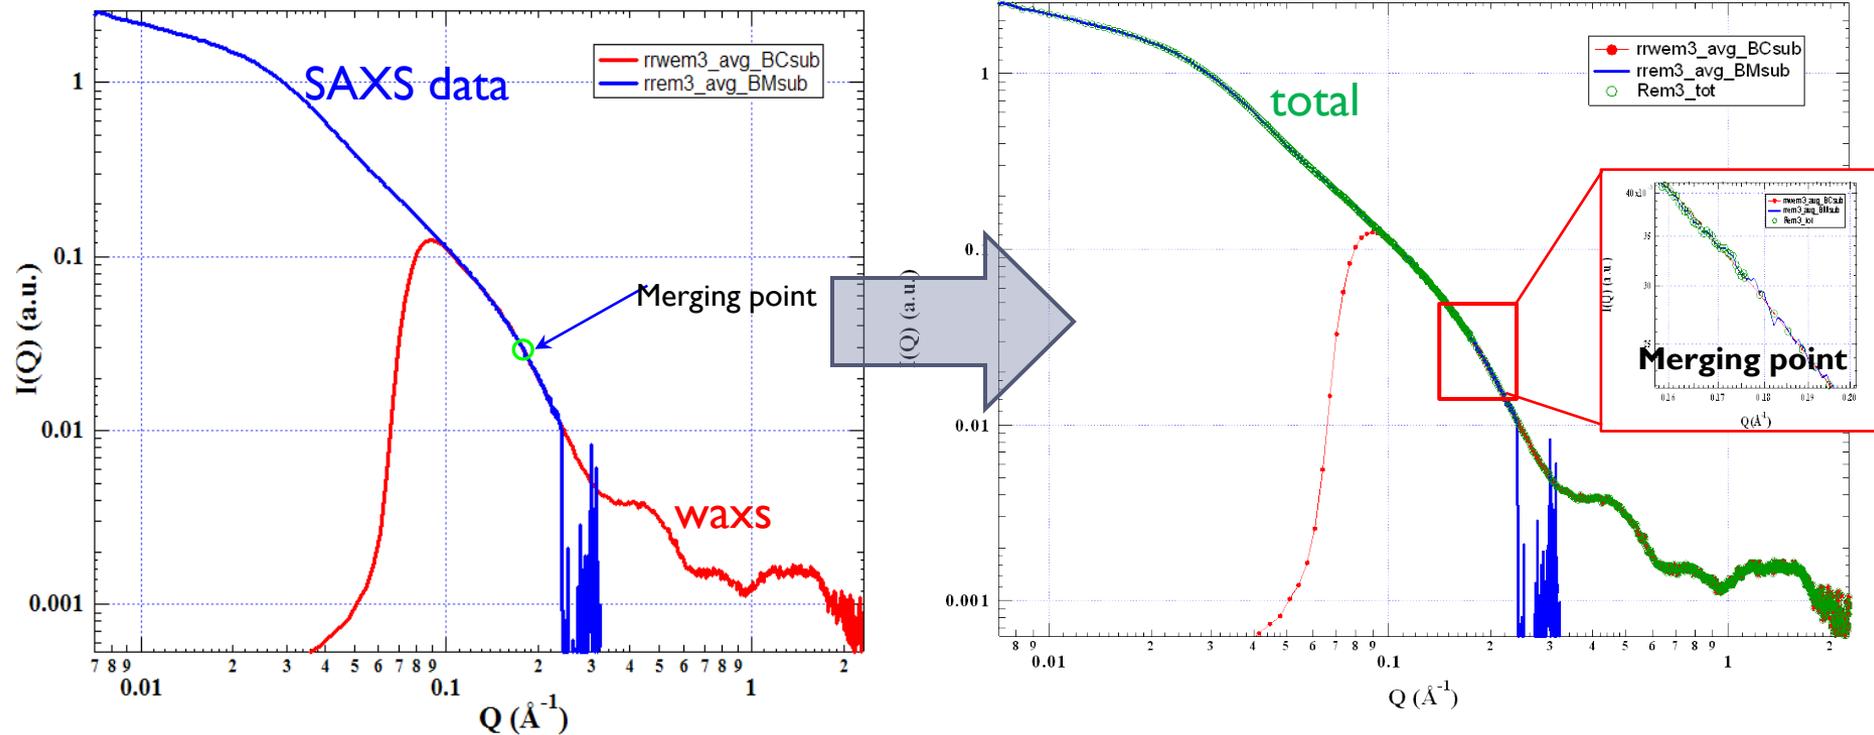

- No negative intensities
- No solvent peak
- Normal high angle feature
- Smooth baseline

# Data quality evaluation: background mis-match

Solution X-ray scattering measurements are very sensitive to the background match. Here is an example of a dilute sample with slightly background mis-match

# SAXS and WAXS data merging

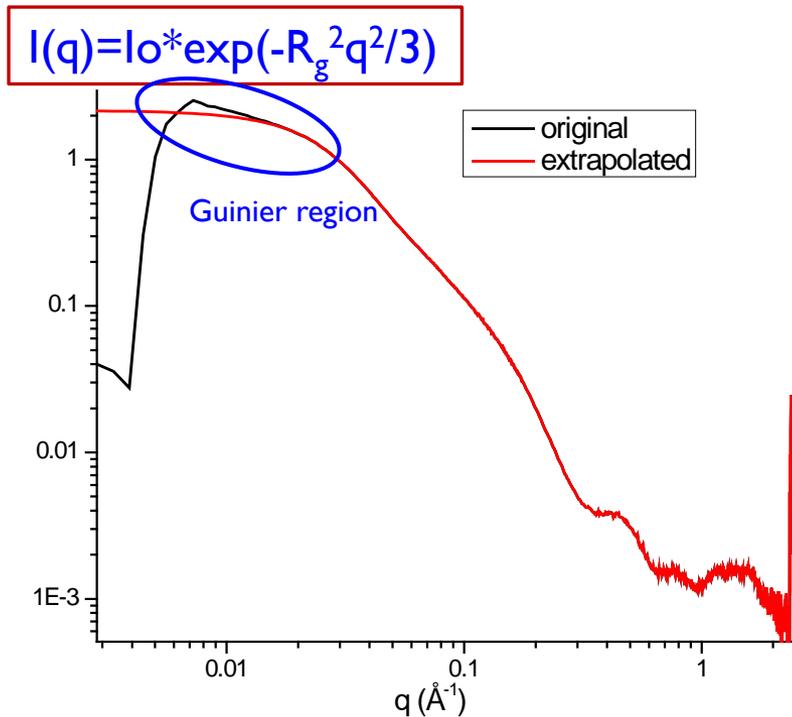

Choose merging point ( $q_M$ ), then take data lower than  $q_M$  from SAXS data set (blue) and higher than  $q_M$  from WAXS data set (red) to form the new data set with complete  $q$  range (total, green).

Igor procedure available

# Additional data manipulations

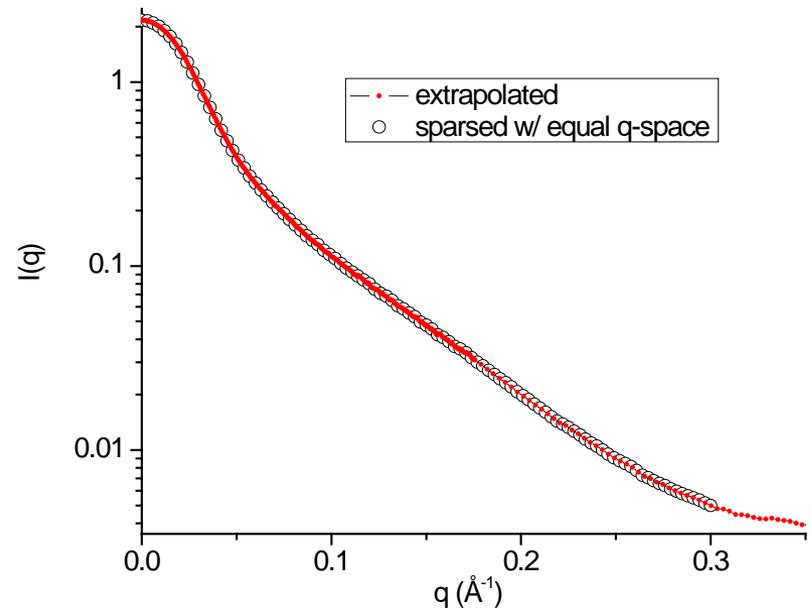

Data extrapolation  $q \rightarrow 0$

For data with good Guinier plot, it is worthy to extrapolate data to  $q \rightarrow 0$ , particularly for large biomolecules.

Origin scripts available

Data points sparsing w/ equal  $q$ -space or equal  $\ln(q)$ -space

The data point densities from SAXS and WAXS are different. Data with equal  $q$ - $\ln(q)$ -space to receive same consideration while further data analysis

matlab scripts available
